EECS 370 - Lecture 12

Introduction to Pipelining

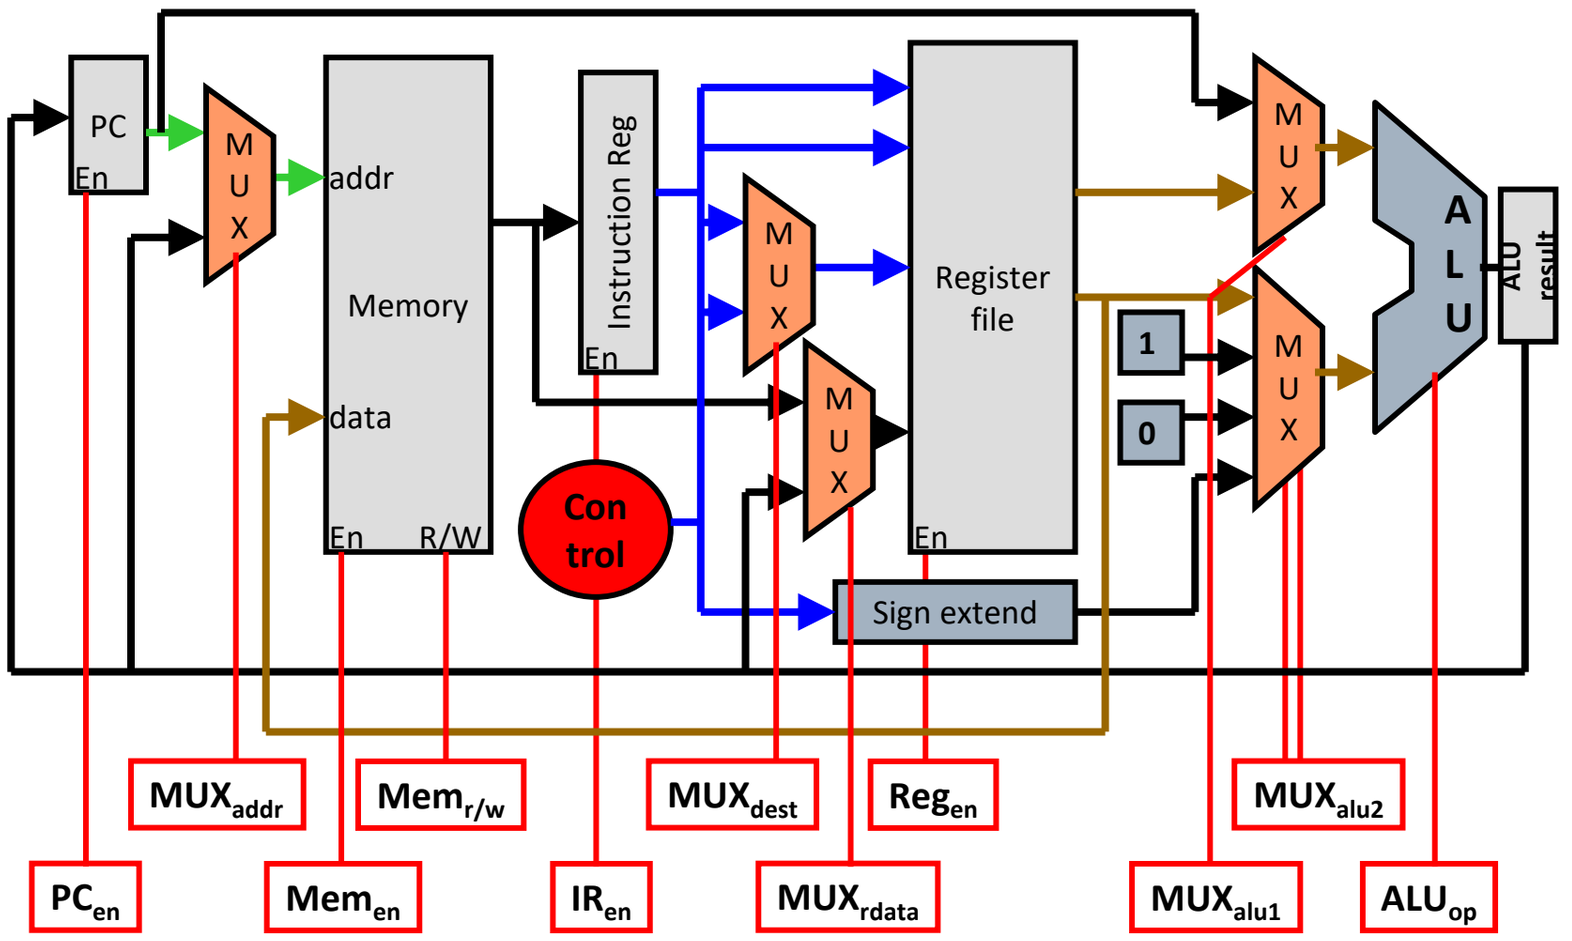
Announcements

- P2
  - Two parts: part a is due **Thu 2/16**
- HW 3
  - Posted on website, due **Mon 2/20**
  - **3 submissions on Gradescope**
    - Individual part
    - Group part
    - Practice exam (also group)
- Midterm exam **Thu March 9, 7-9pm**
  - Sample exams on website
  - Up through pipelining covered

Review: What's Wrong with Single-Cycle?

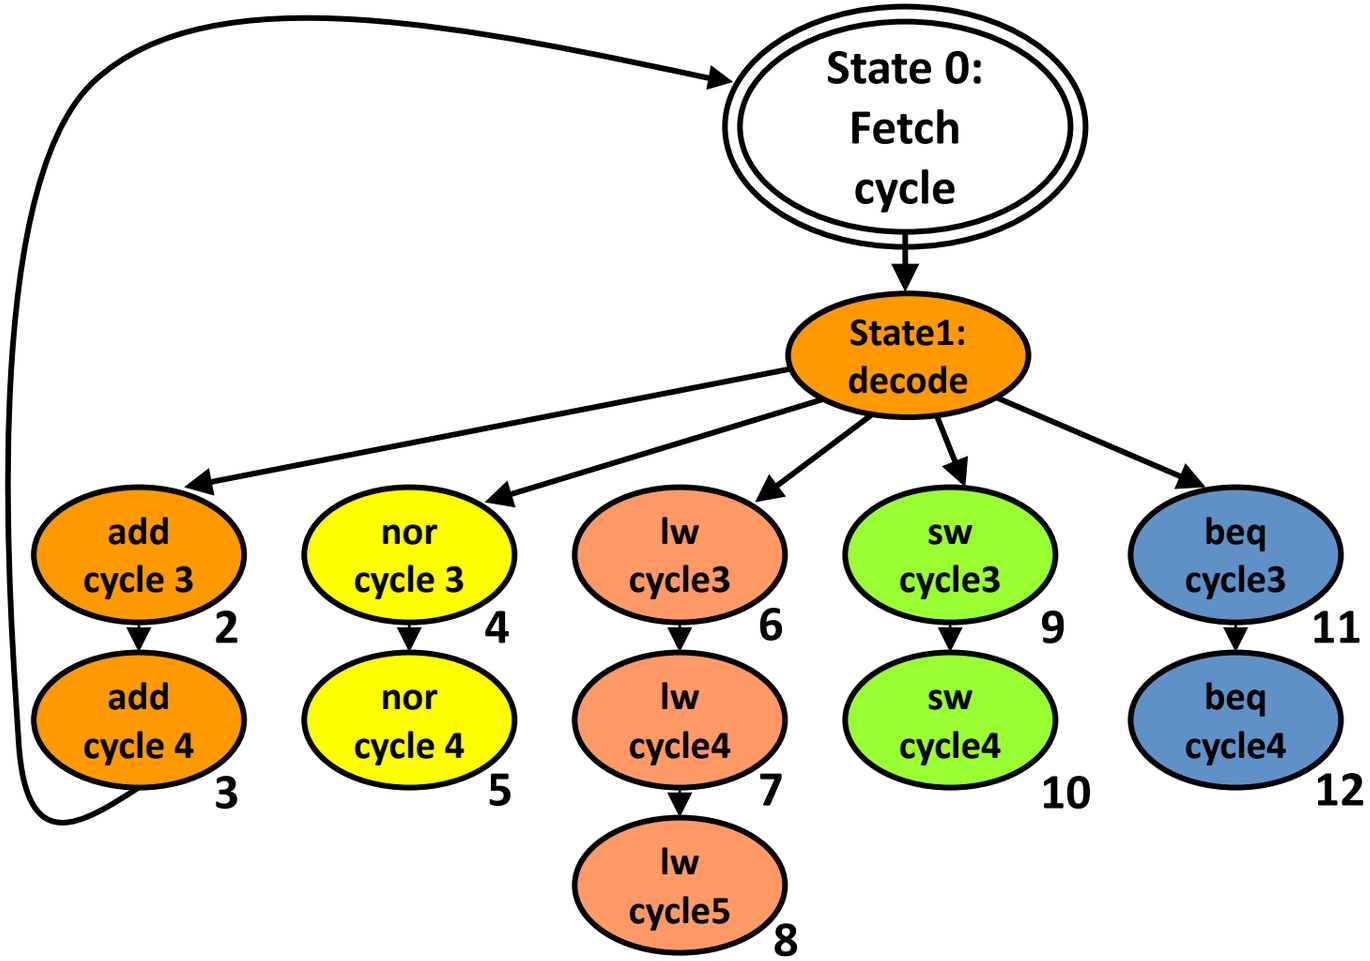
- **All instructions run at the speed of the slowest instruction.**
- Adding a long instruction can hurt performance
  - What if you wanted to include multiply?
- You cannot reuse any parts of the processor
  - We have 3 different adders to calculate PC+1, PC+1+offset and the ALU
- No benefit in making the common case fast
  - Since every instruction runs at the slowest instruction speed
    - This is particularly important for loads as we will see later

Review Multi-cycle LC2K Datapath



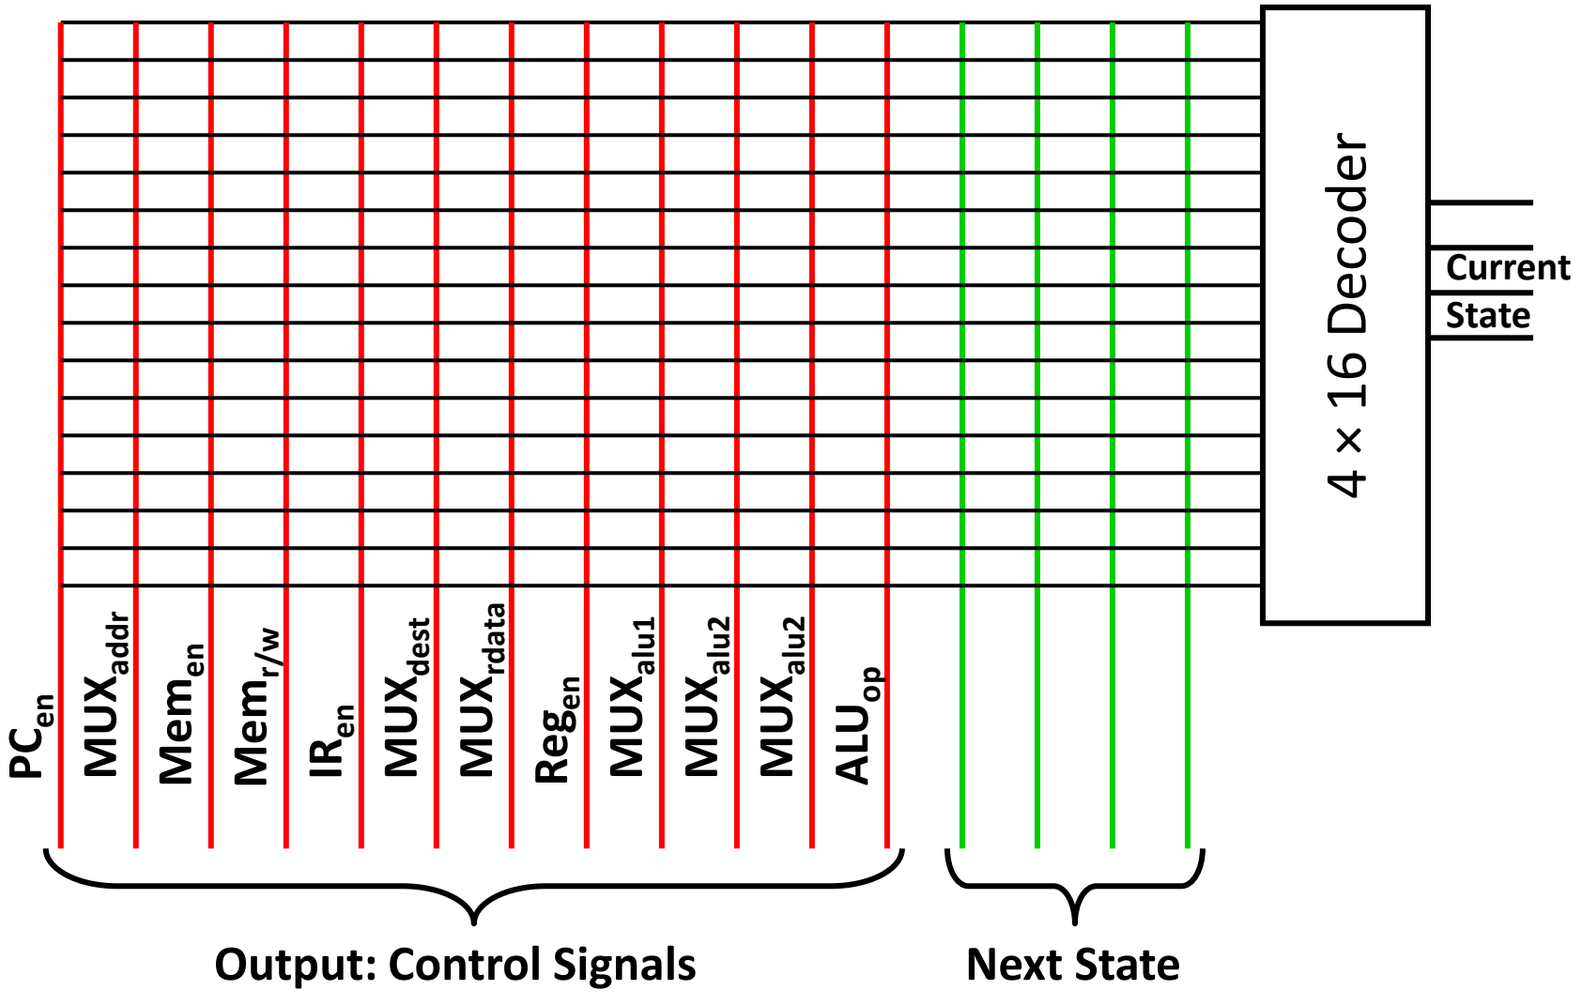
Each red signal comes from "Control" (implemented via ROM as before)

State machine for multi-cycle control signals (transition functions)



Note: we aren't worrying about JALR instruction in hardware going forward

Building the Control ROM

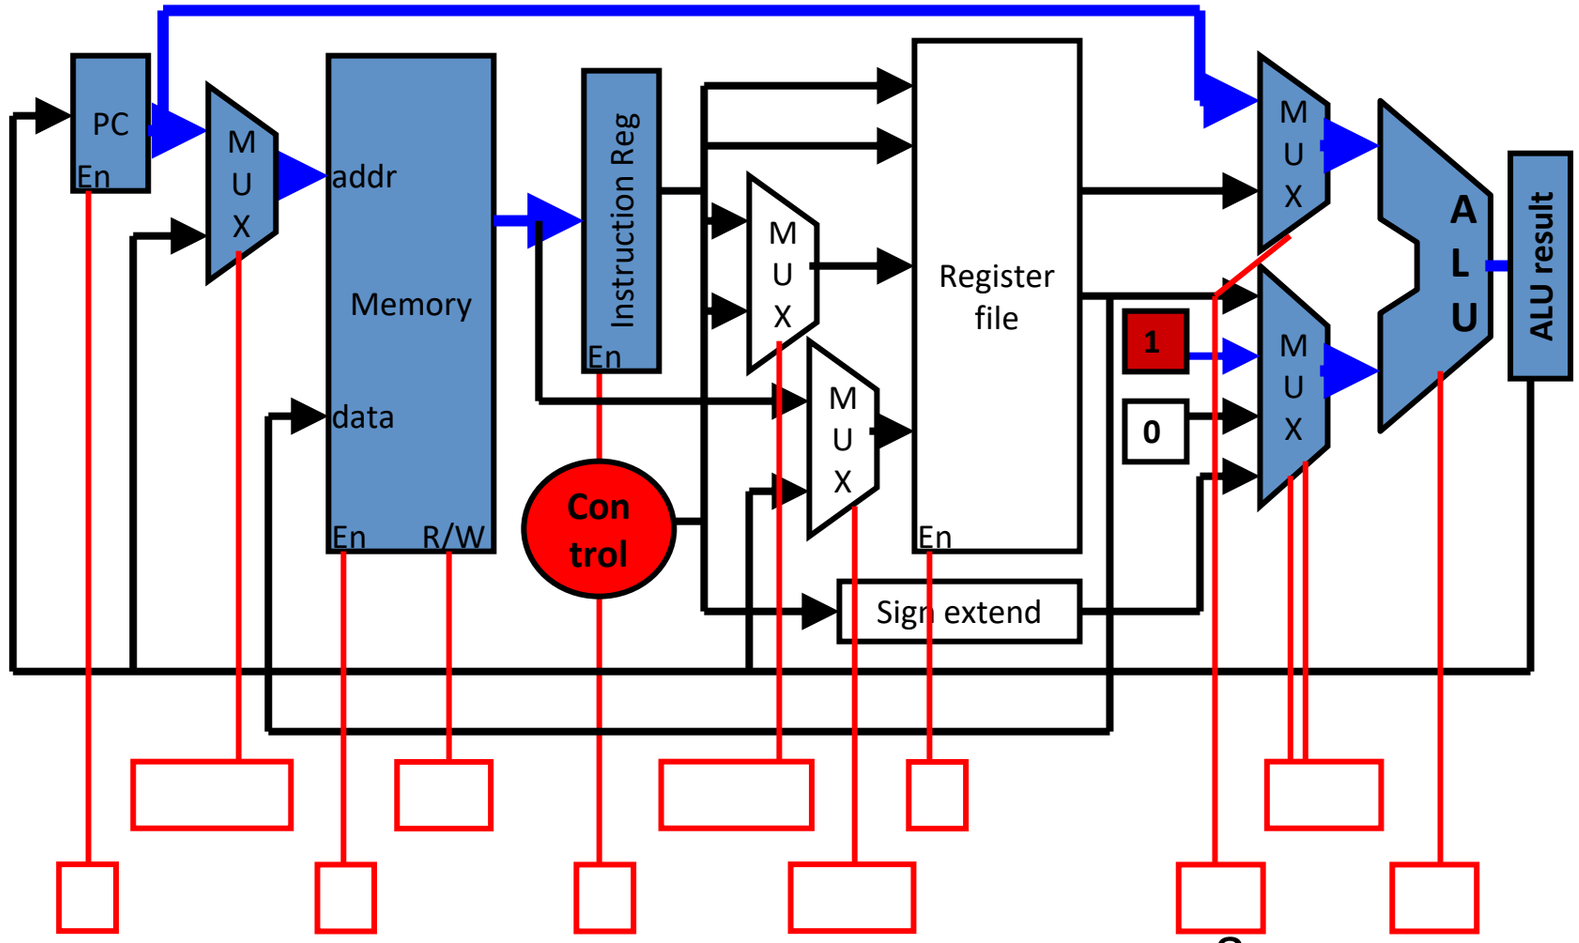


First Cycle (State 0) Fetch Instr

- What operations need to be done in the first cycle of executing any instruction?
  - Read memory[PC] and store into instruction register.
    - Must select PC in memory address MUX ($MUX_{addr} = 0$)
    - Enable memory operation ($Mem_{en} = 1$)
    - R/W should be (read) ($Mem_{r/w} = 0$)
    - Enable Instruction Register write ($IR_{en} = 1$)
  - Calculate PC + 1
    - Send PC to ALU ($MUX_{alu1} = 0$)
    - Send 1 to ALU ($MUX_{alu2} = 01$)
    - Select ALU add operation ($ALU_{op} = 0$)
  - $PC_{en} = 0$; $Reg_{en} = 0$; MUX_{dest} and $MUX_{rdata} = X$
- Next State: Decode Instruction

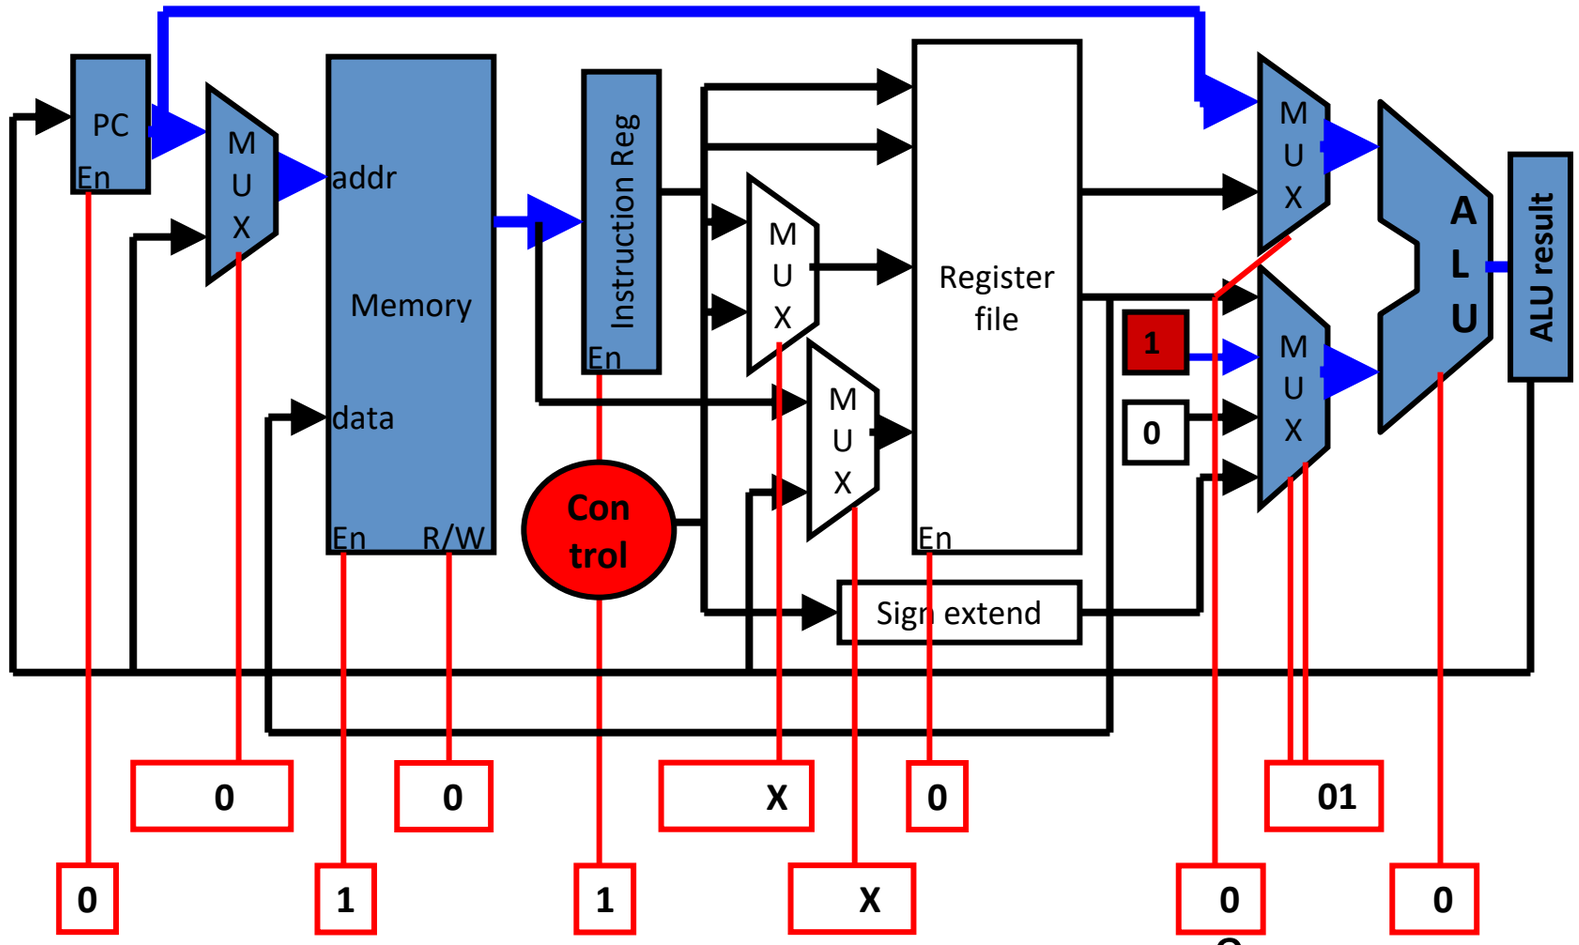
First Cycle (State 0) Fetch Instr

This is the same for all instructions
(since we don't know the instruction yet!)

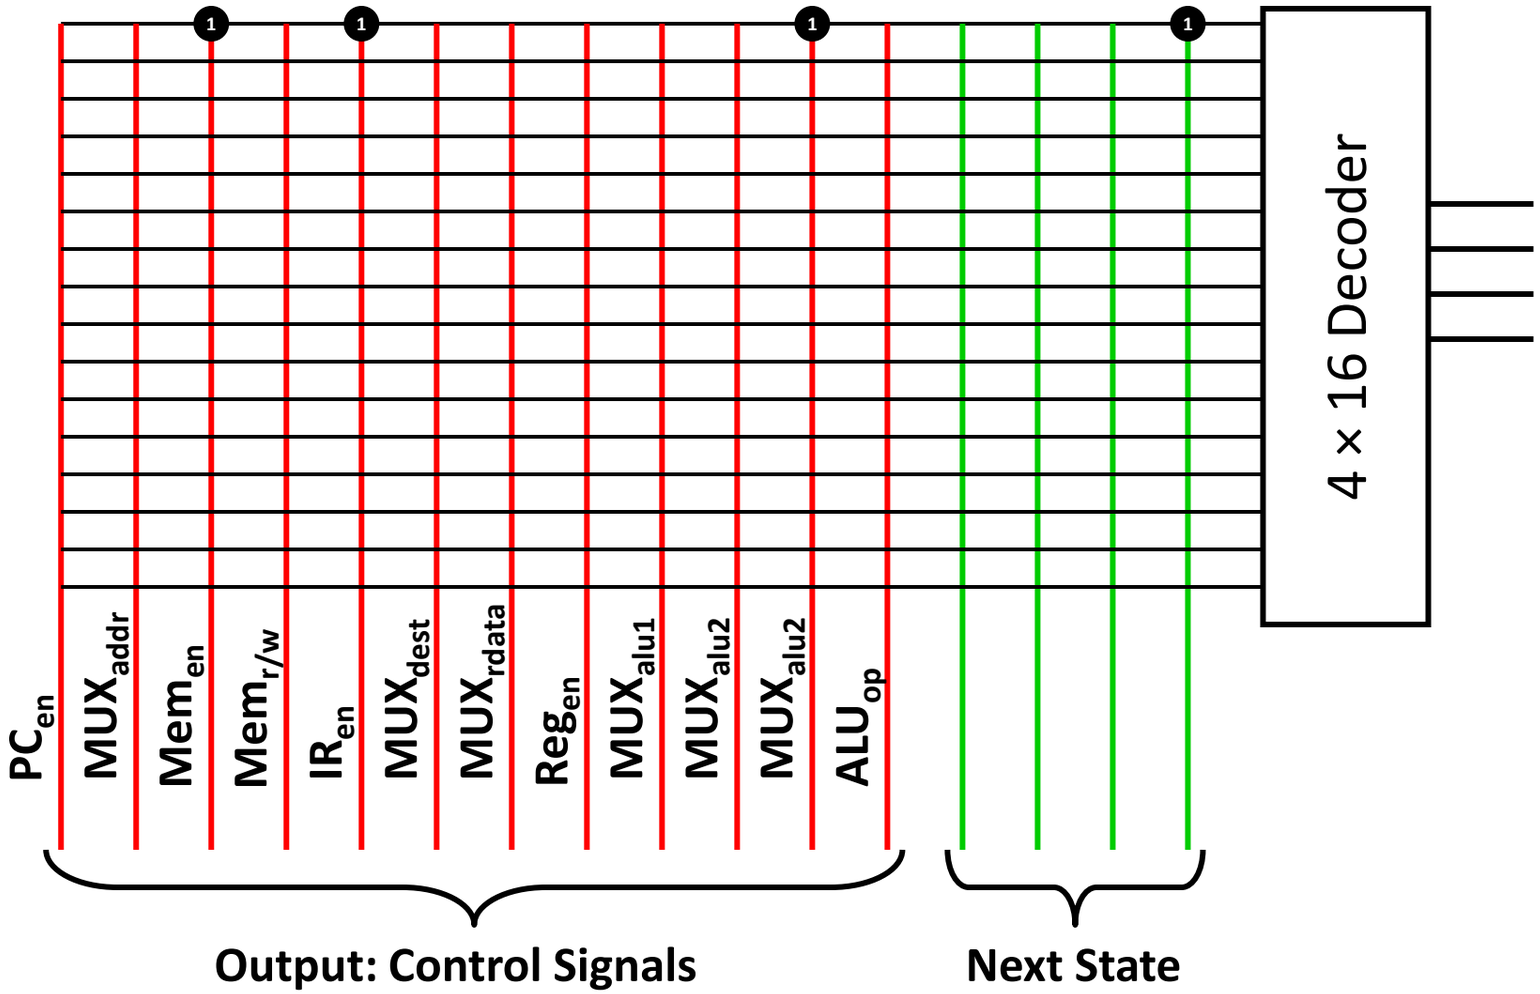


First Cycle (State 0) Fetch Instr

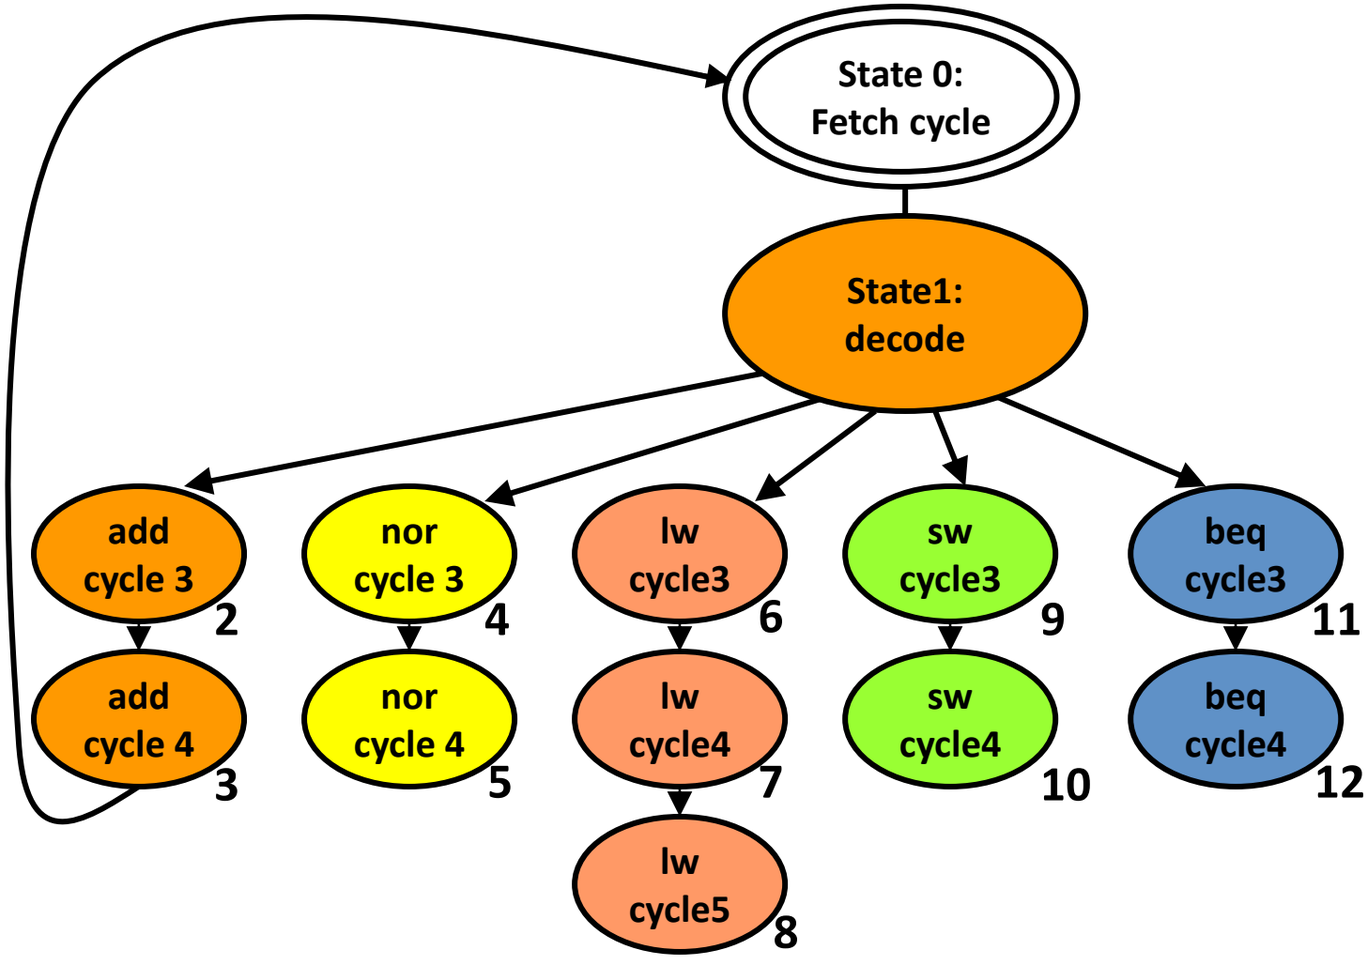
This is the same for all instructions
(since we don't know the instruction yet!)



Building the Control ROM



State 1: instruction decode

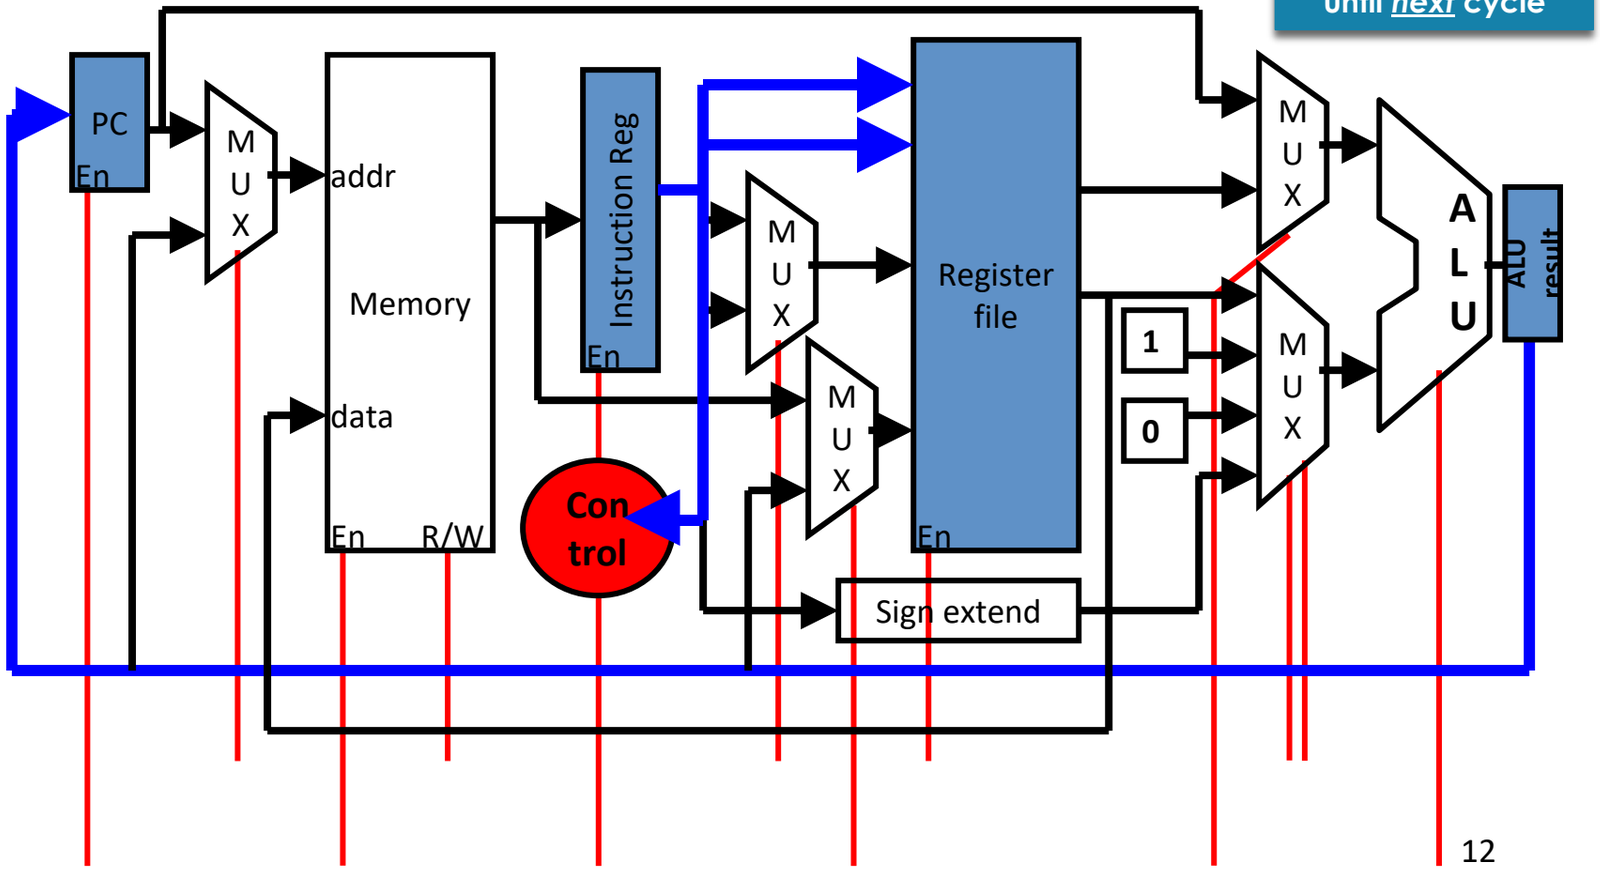


State 1: output function

Poll: What will the control bits be?

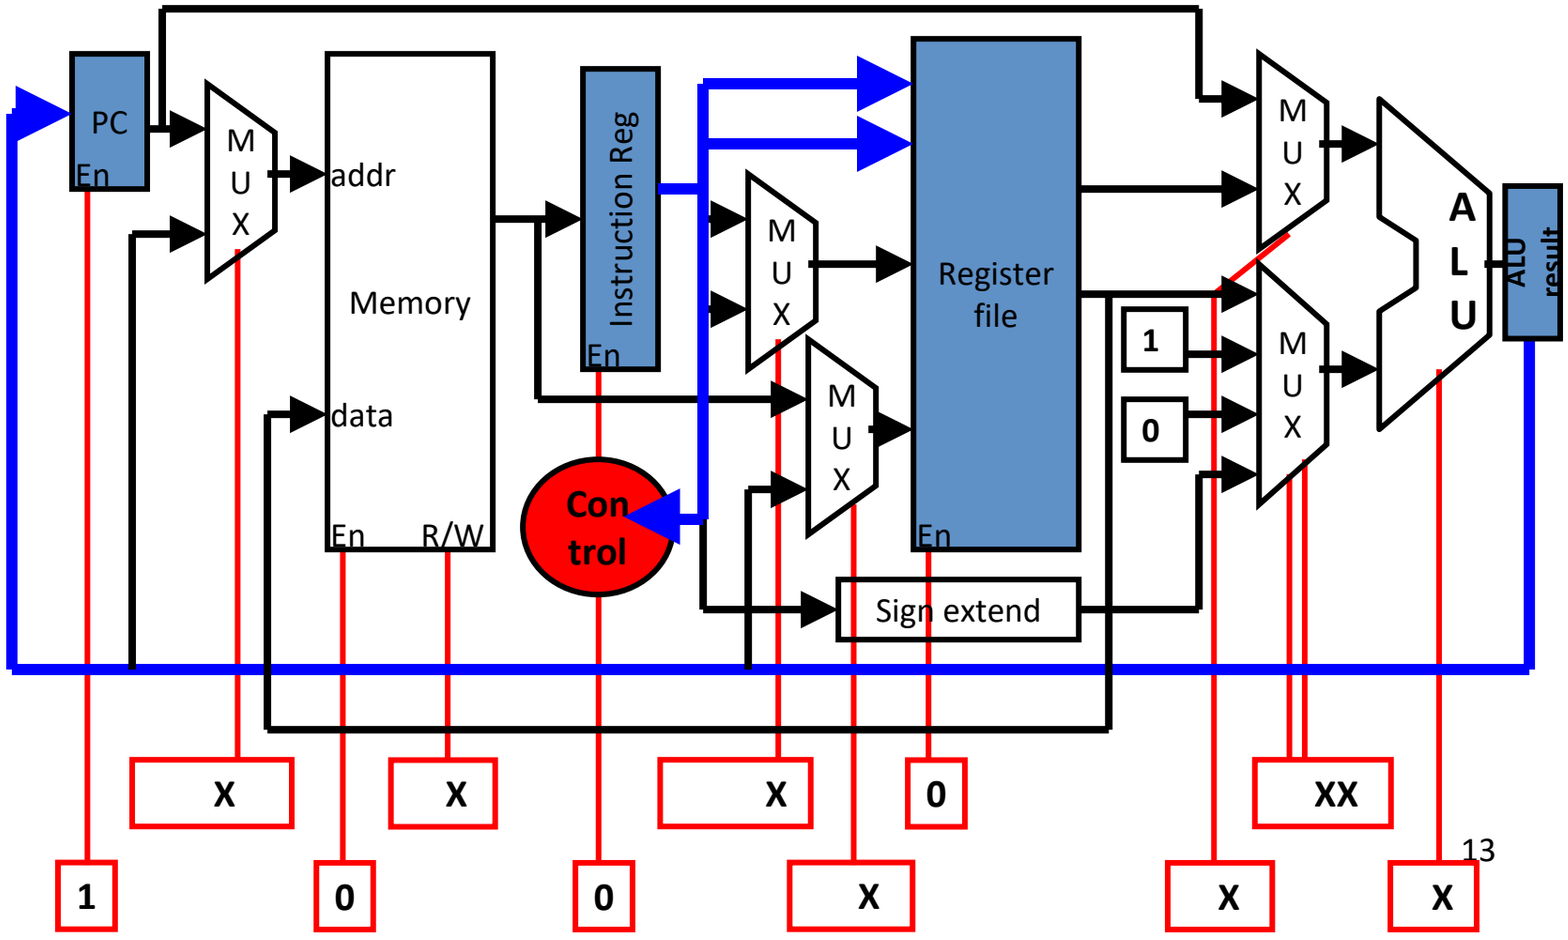
Update PC; read registers (regA and regB); use opcode to determine next state

Note: since RF read latency is same as clock period, RF data isn't available until *next* cycle



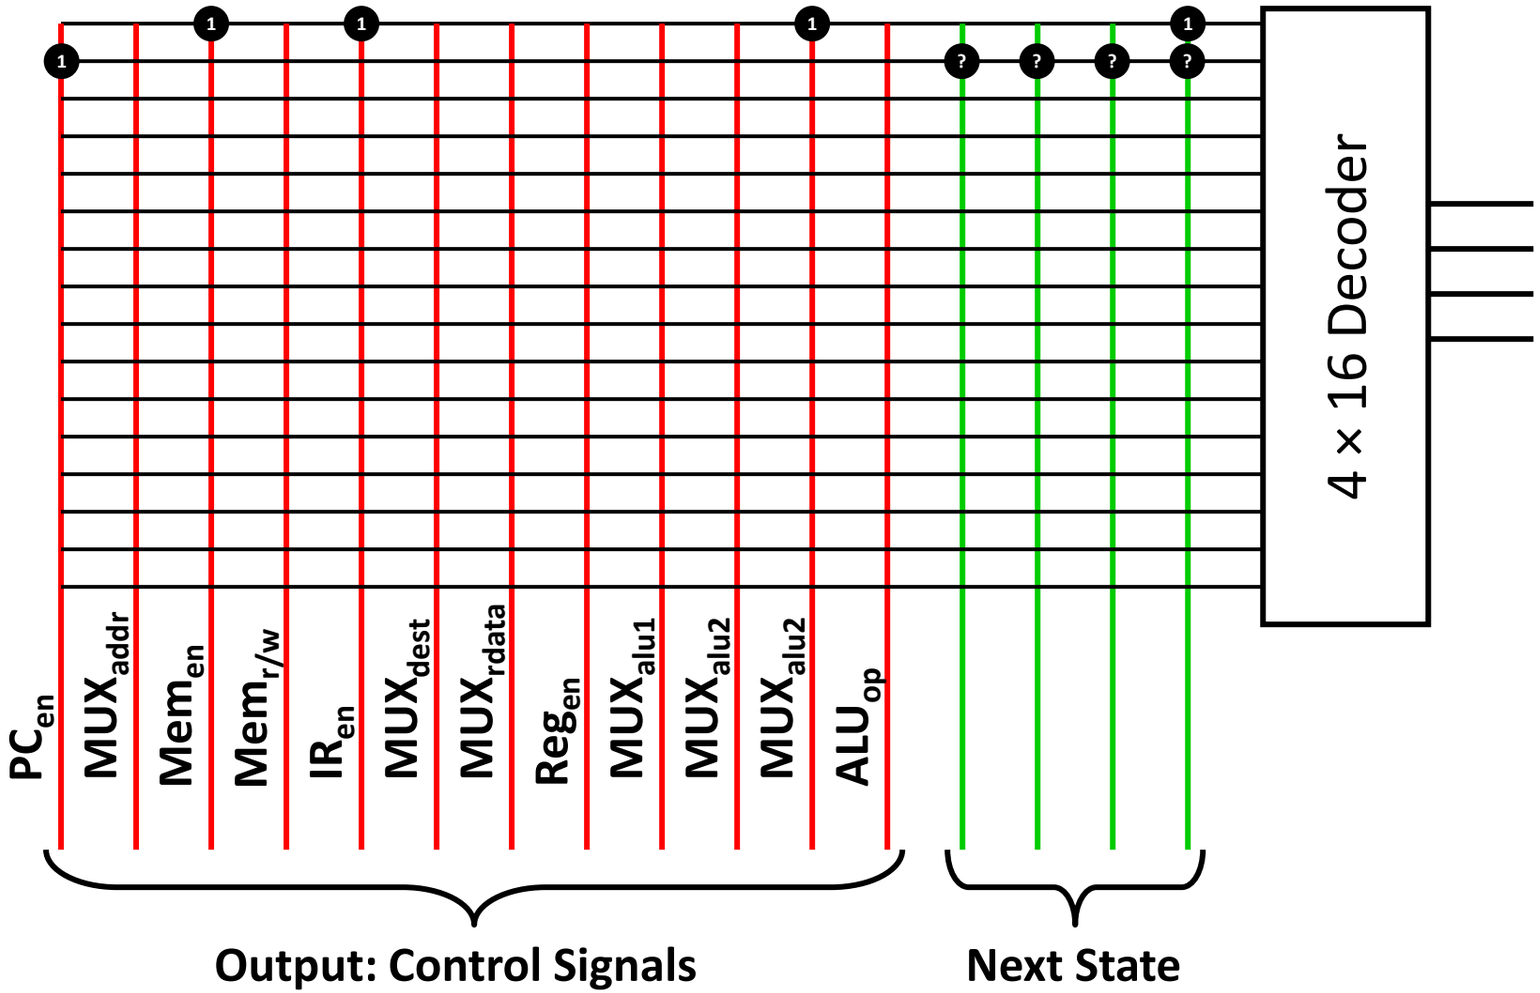
State 1: output function

Update PC; read registers (regA and regB);
use opcode to determine next state

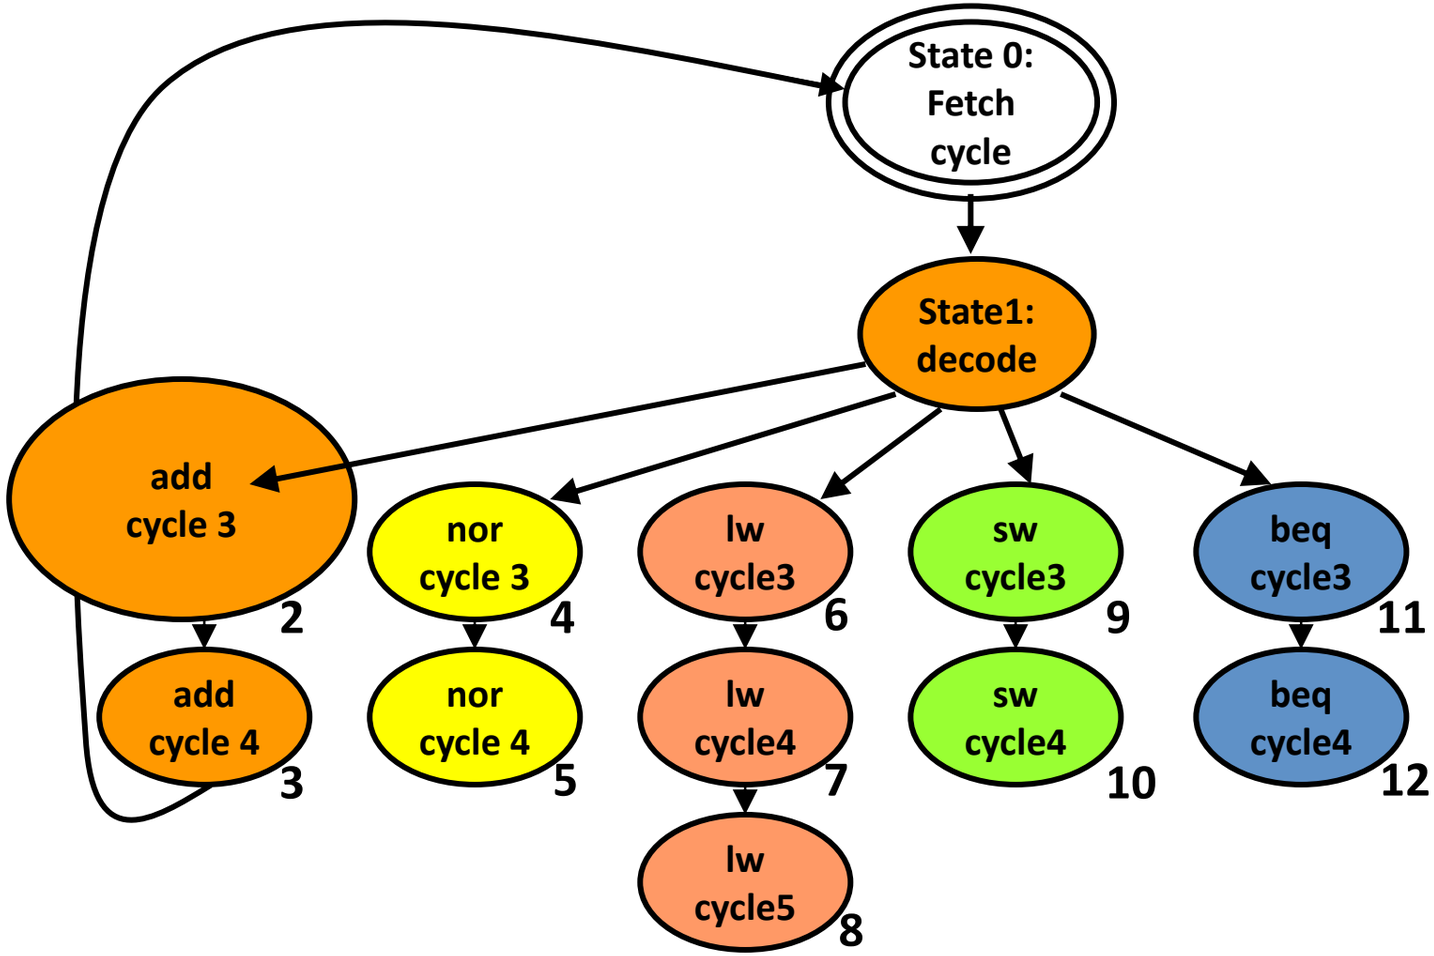


Building the Control ROM

How do we set next state?? Let's come back to that…

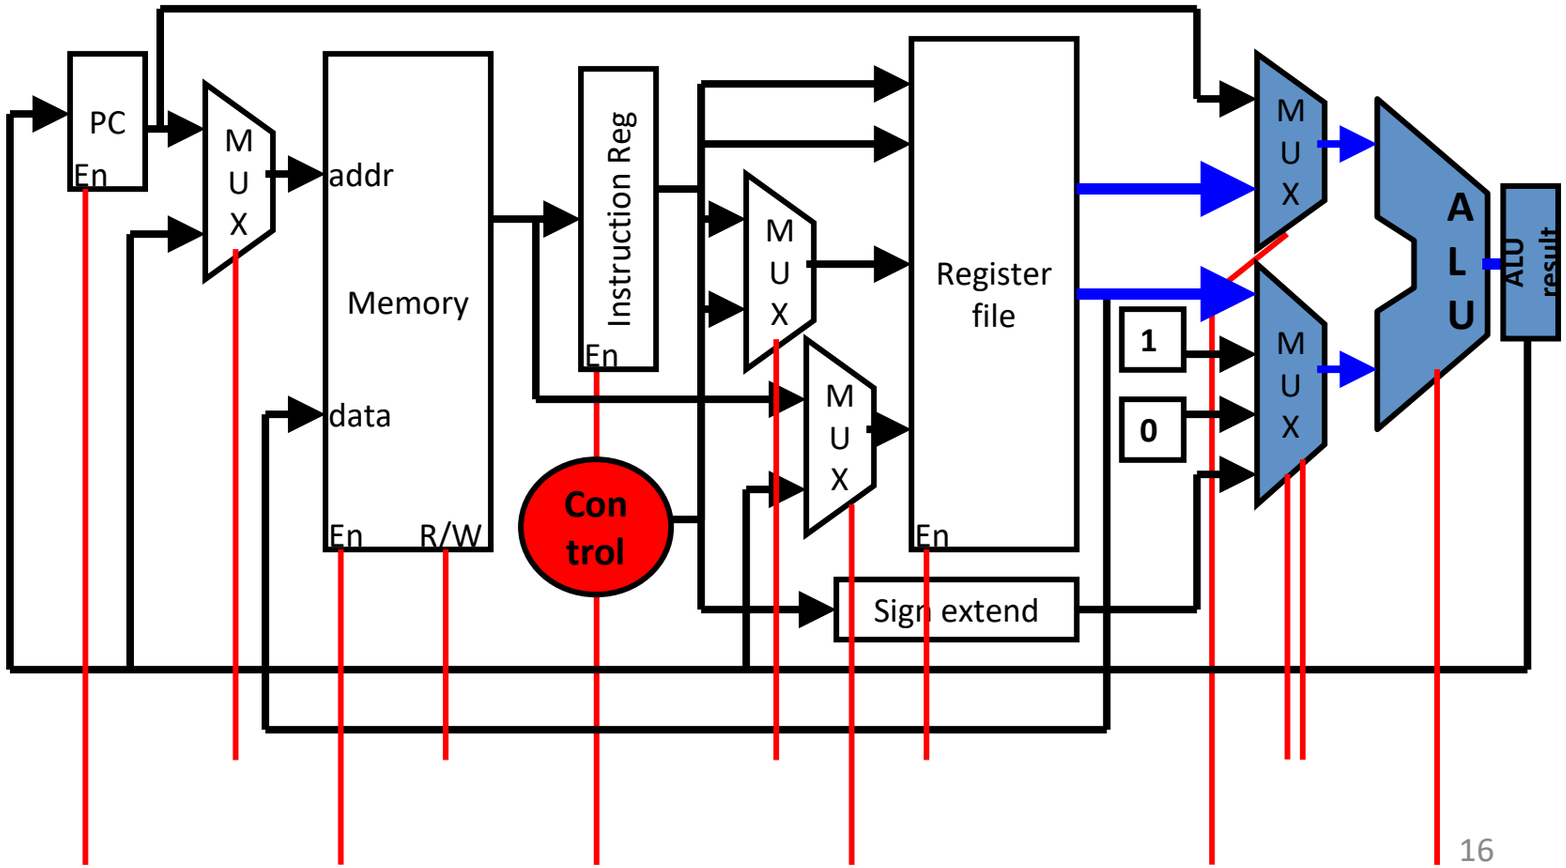


State 2: Add cycle 3



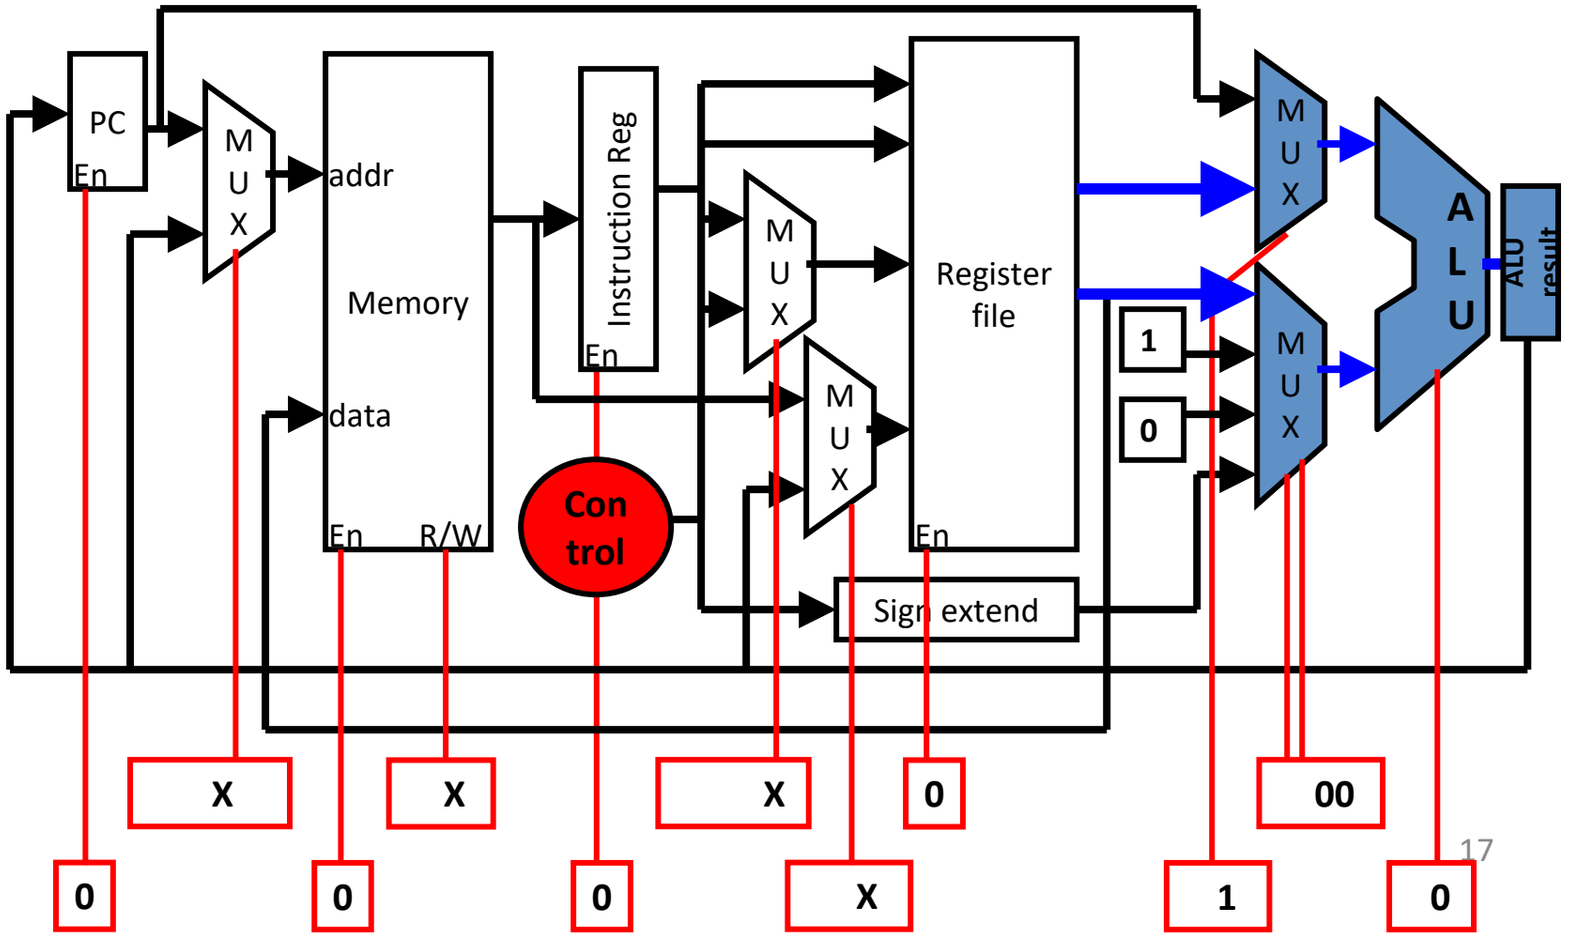
State 2: Add Cycle 3 Operation

Send control signals to MUX to select values of regA and regB and control signal to ALU to add

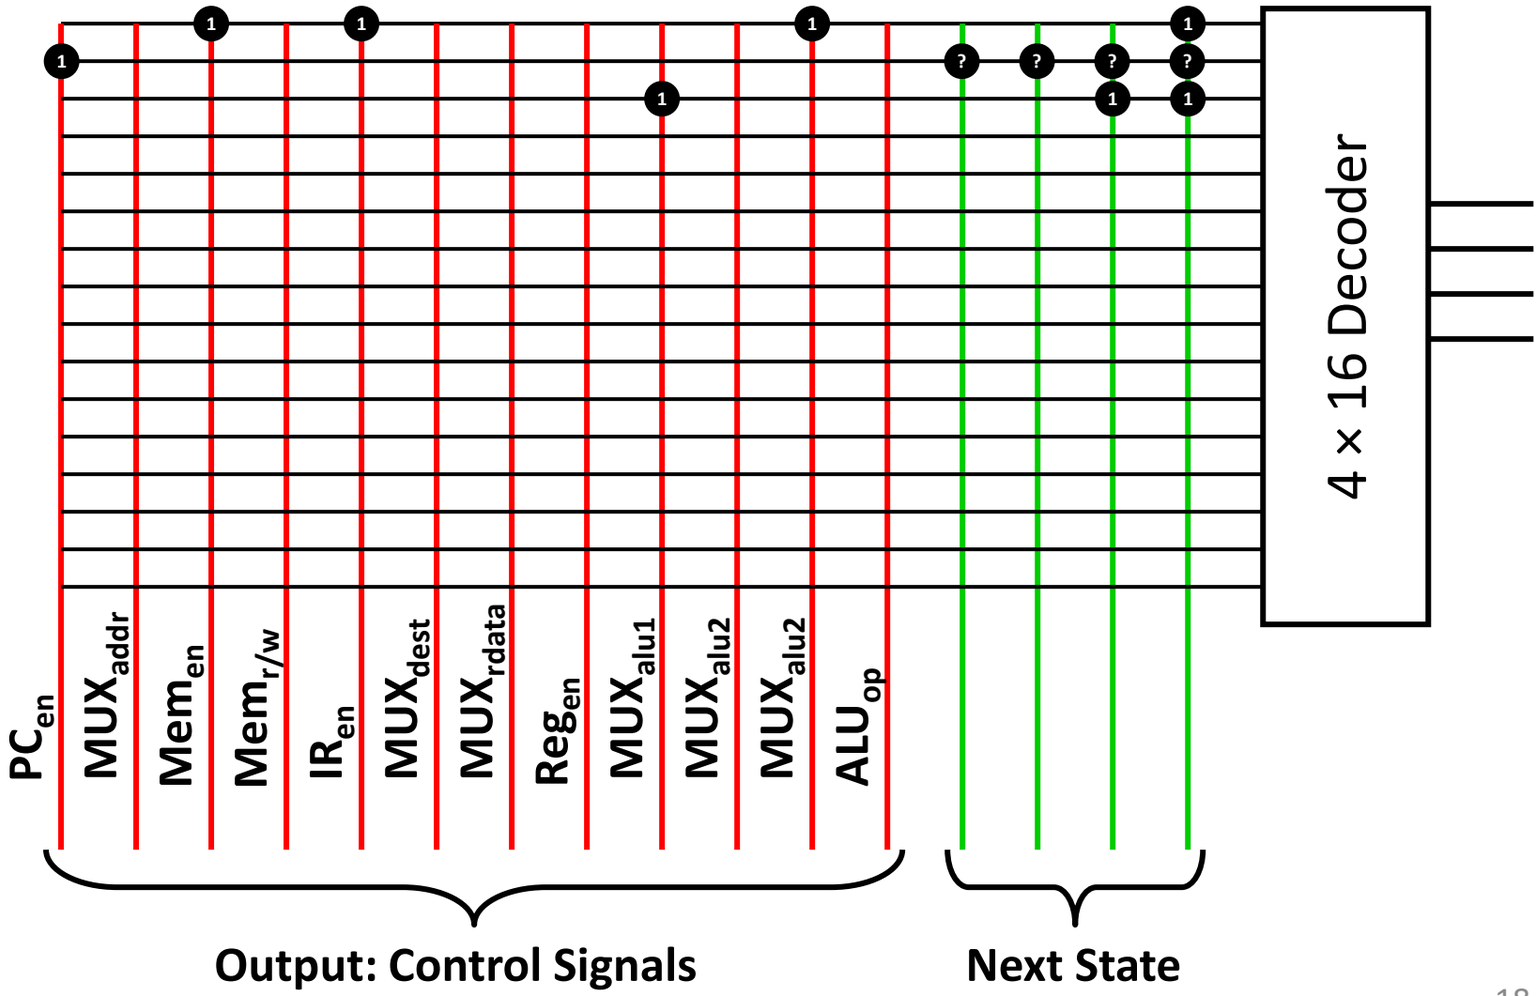


State 2: Add Cycle 3 Operation

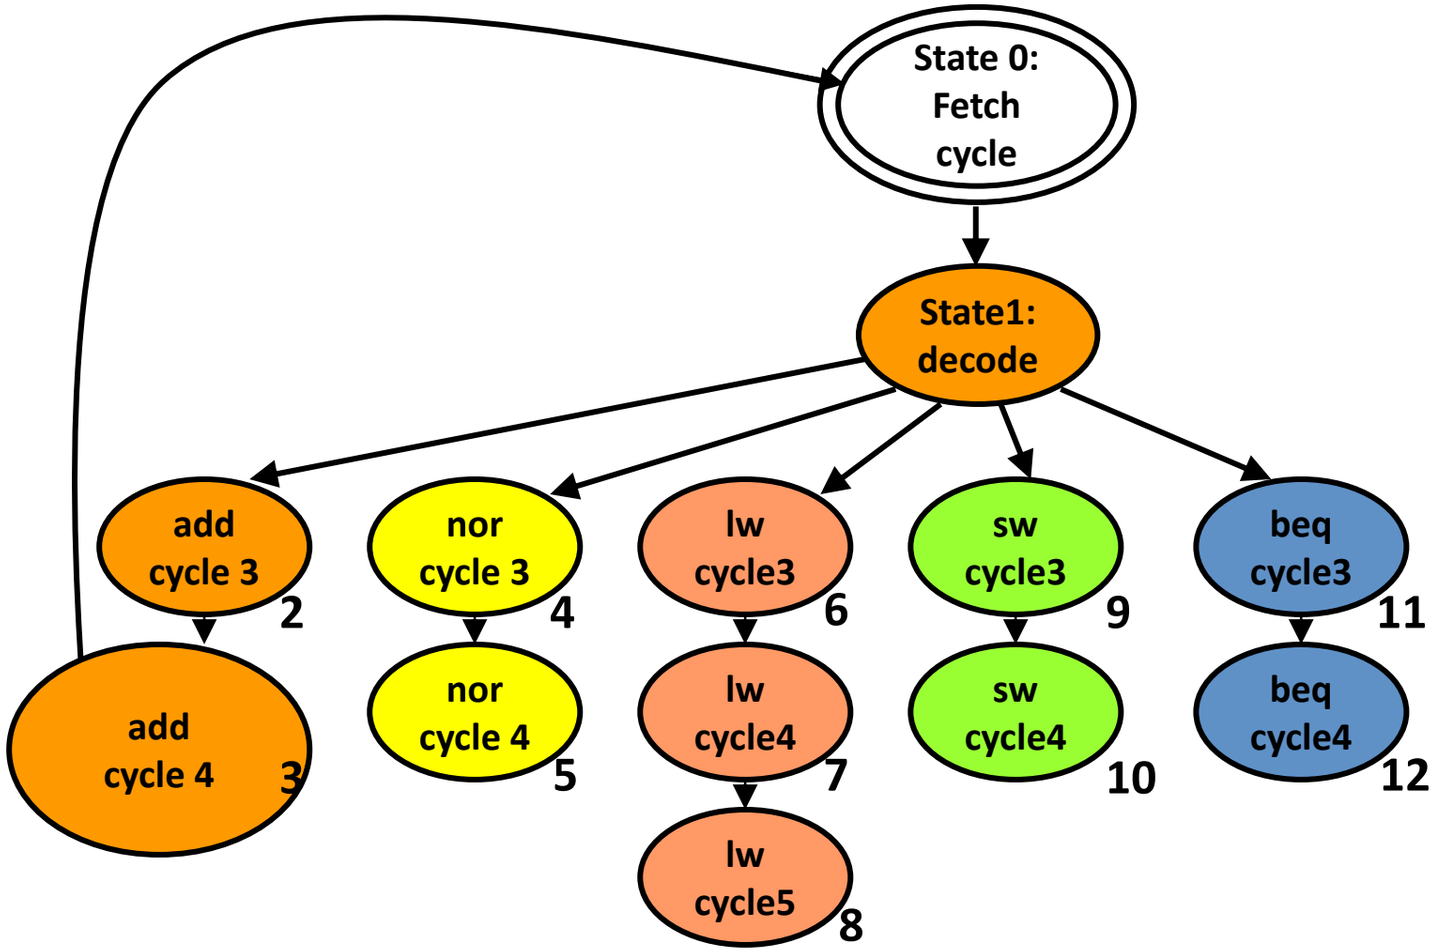
Send control signals to MUX to select values of regA and regB and control signal to ALU to add



Building the Control Rom

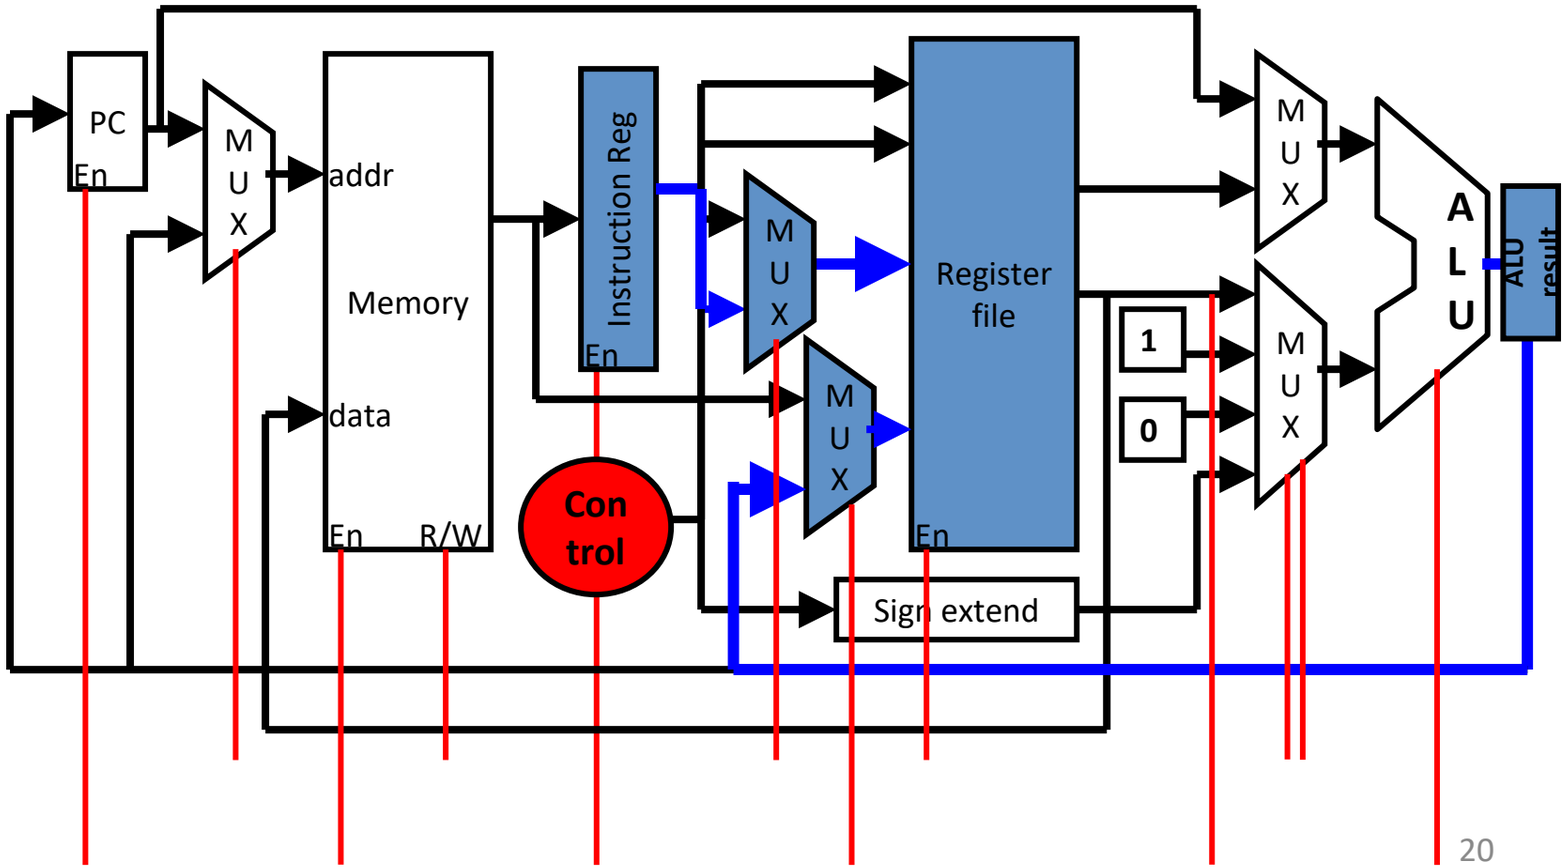


State 3: Add cycle 4



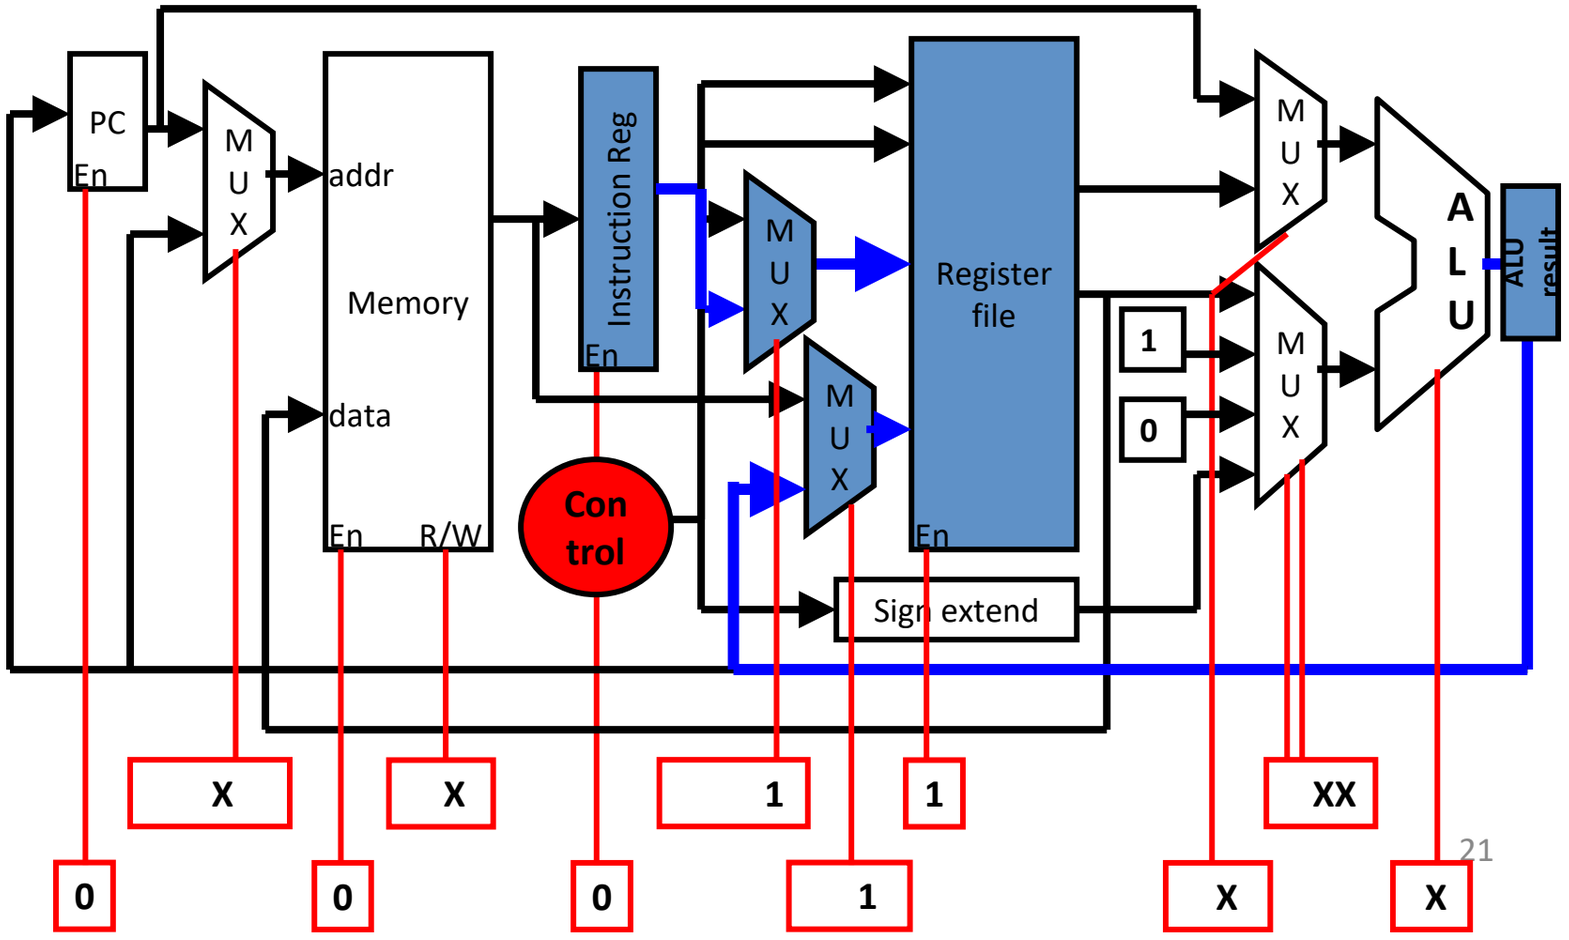
Add Cycle 4 (State 3) Operation

Send control signal to address MUX to select dest and to data MUX to select ALU output, then send write enable to register file.

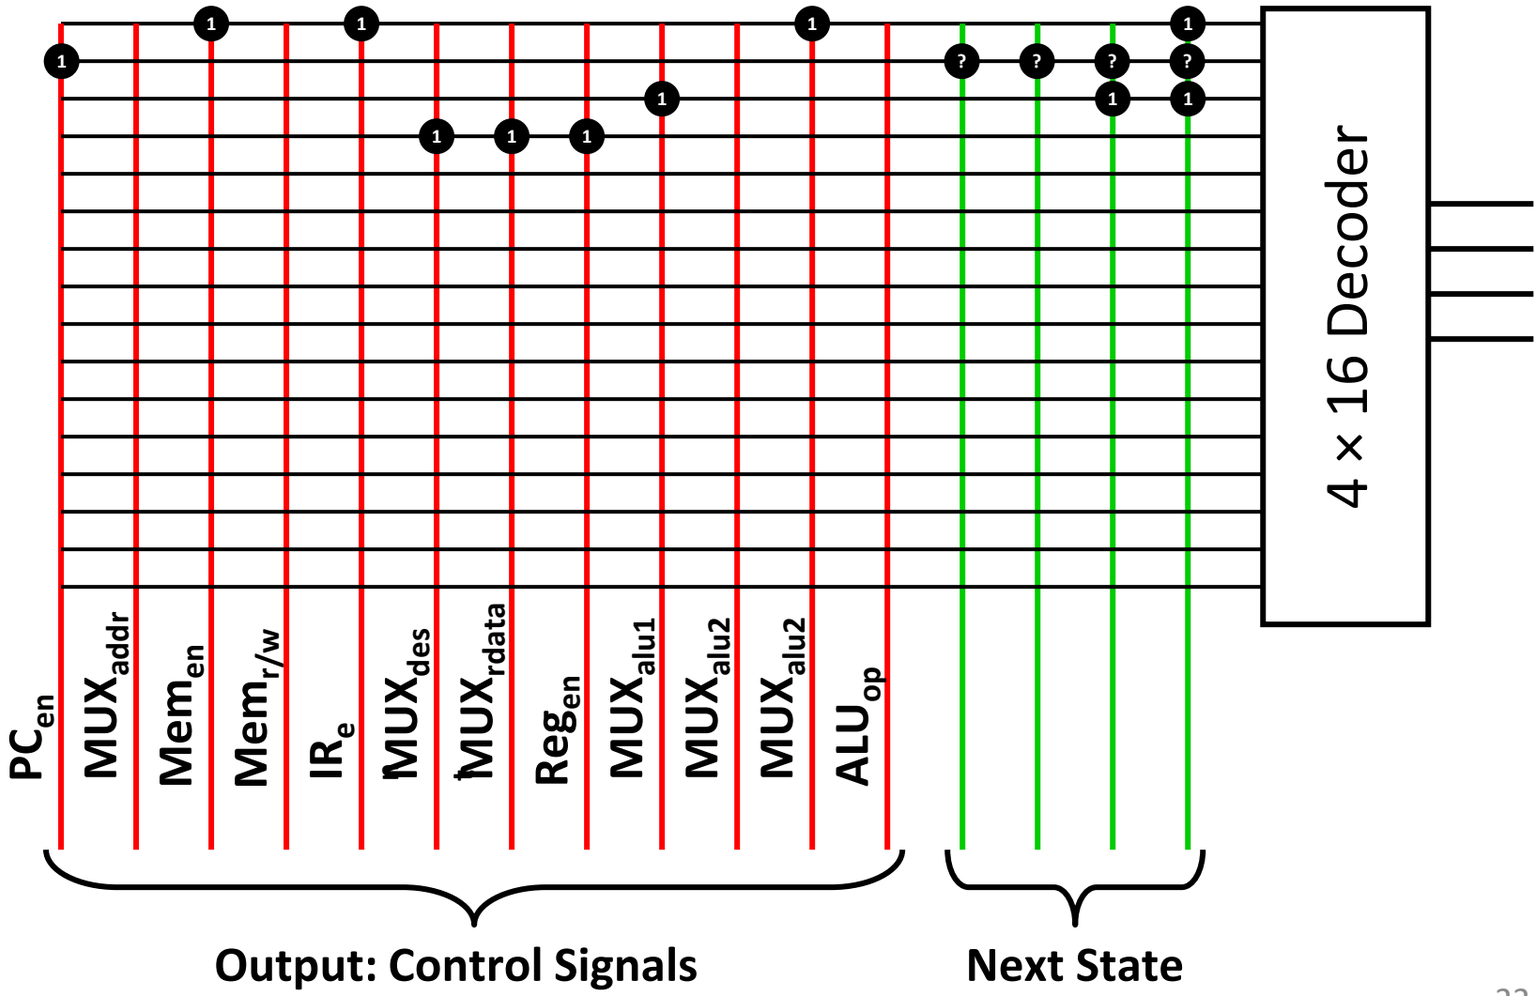


Add Cycle 4 (State 3) Operation

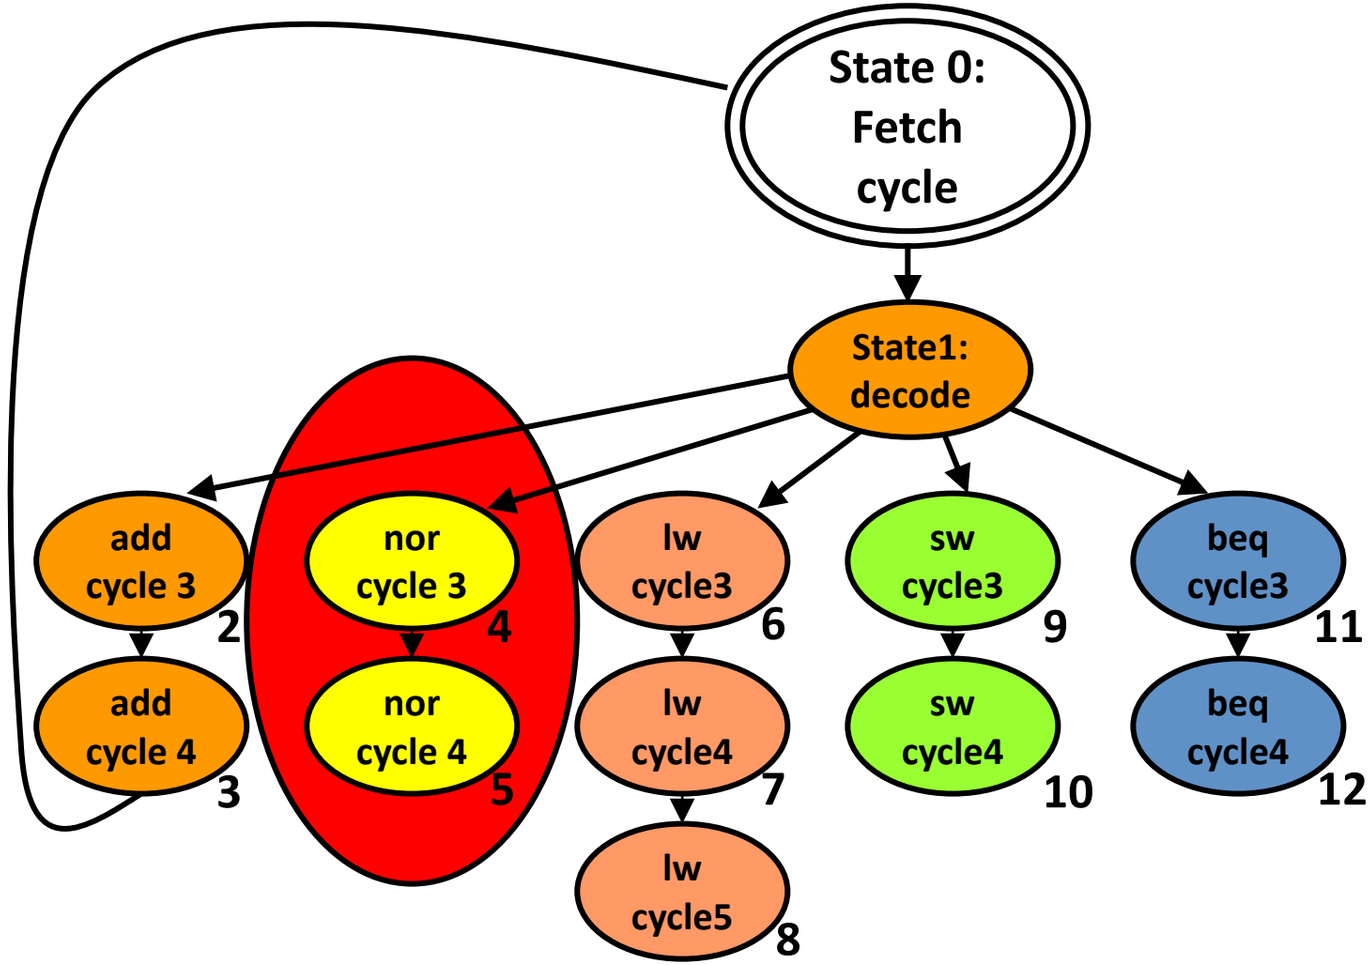
Send control signal to address MUX to select dest and to data MUX to select ALU output, then send write enable to register file.



Building the Control Rom

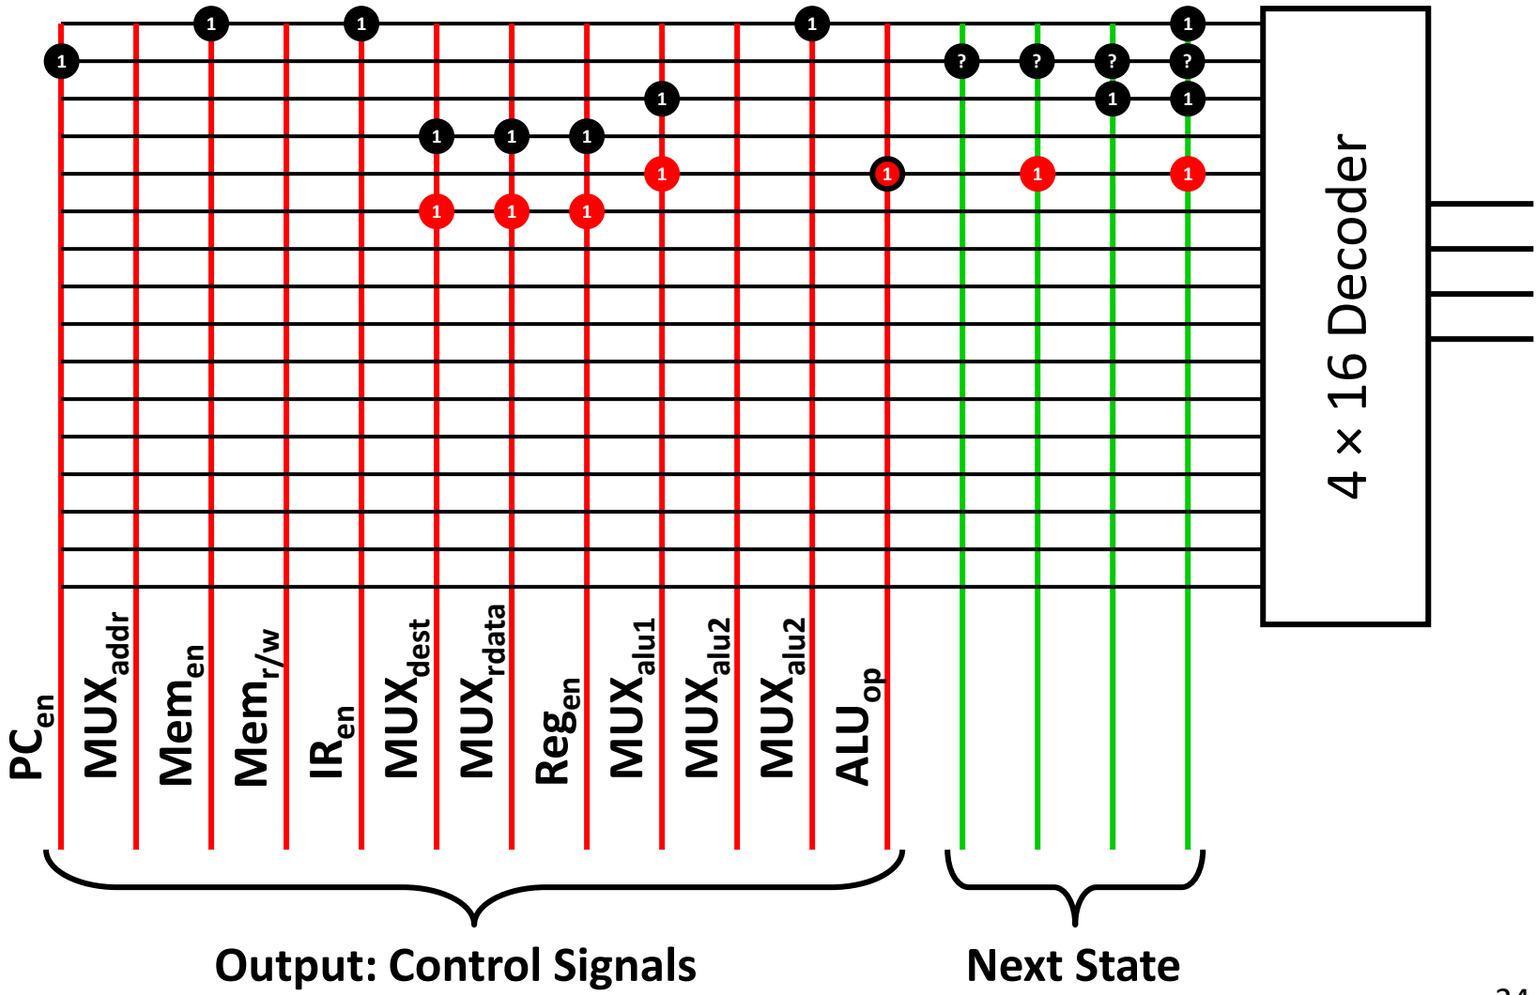


Return to State 0: Fetch cycle to execute the next instruction

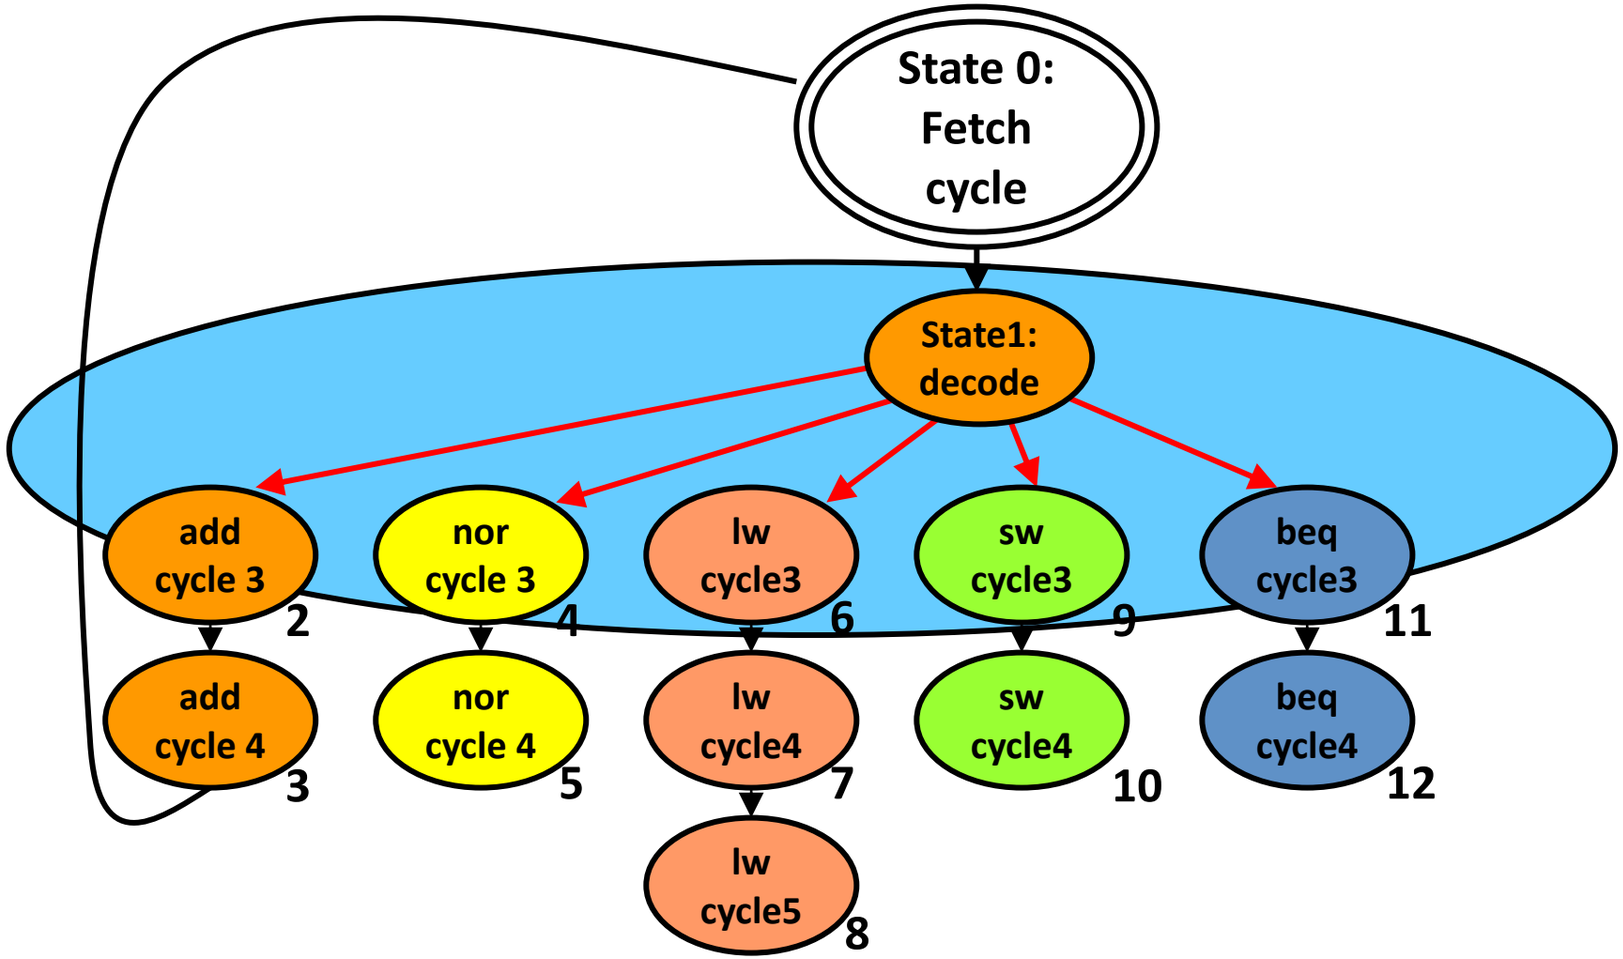


Control Rom for nand (4 and 5)

Same output as add except ALU_{op} and Next State

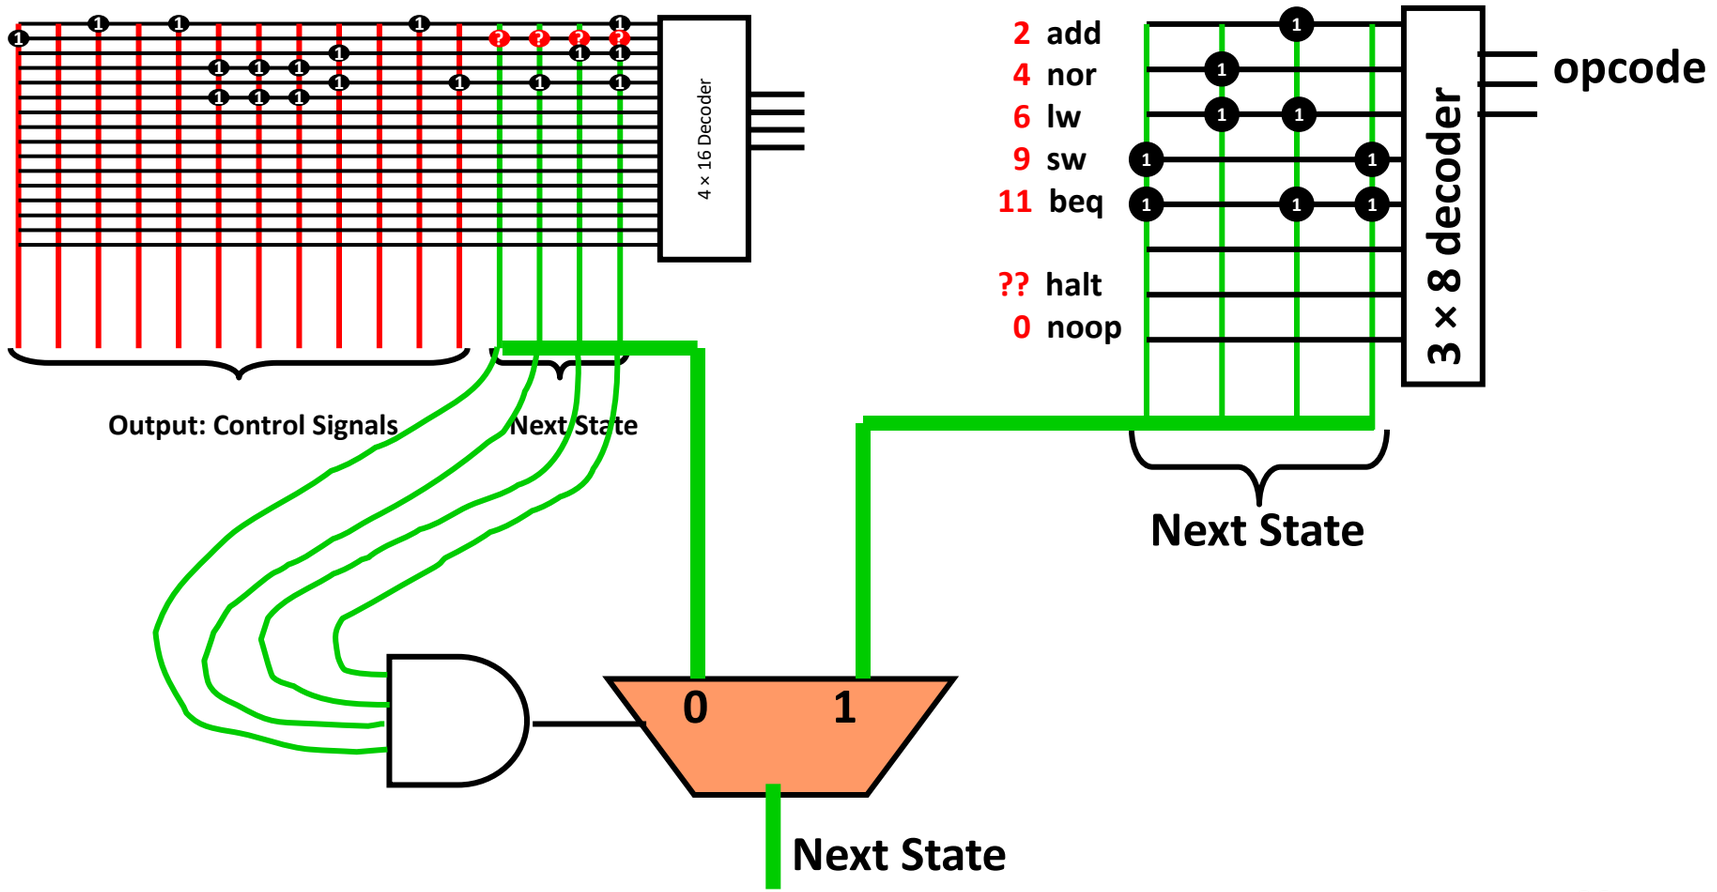


What about the transition from state 1?

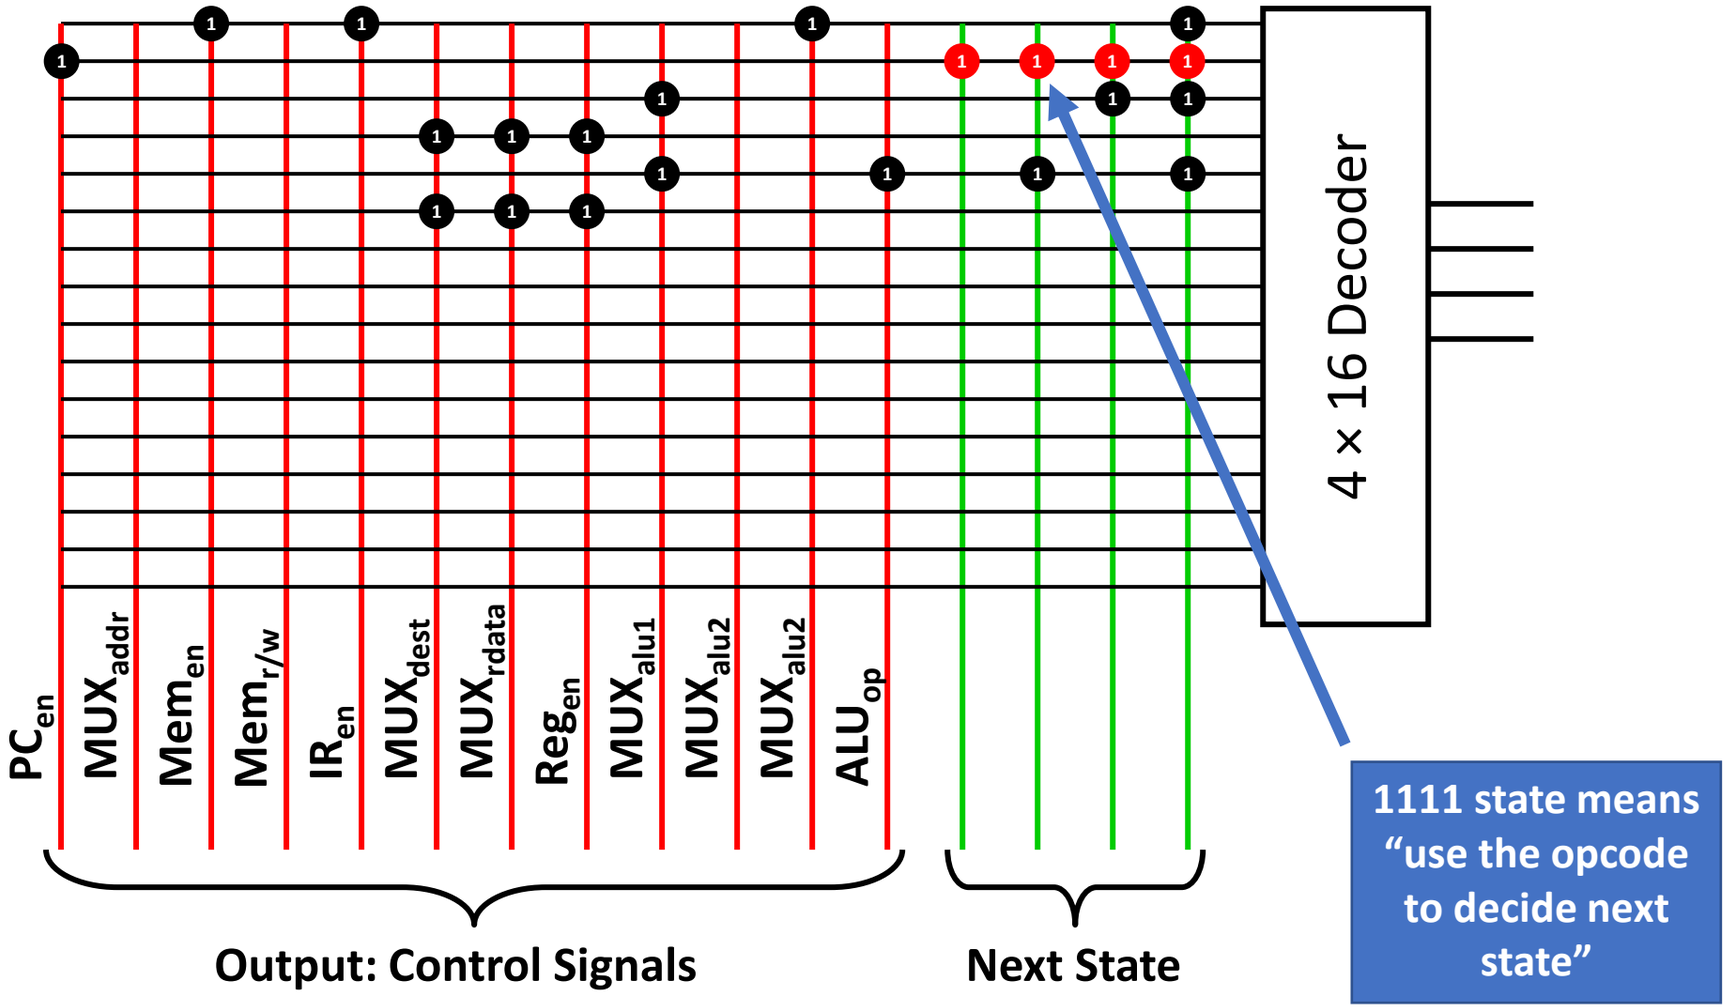


Complete transition function circuit

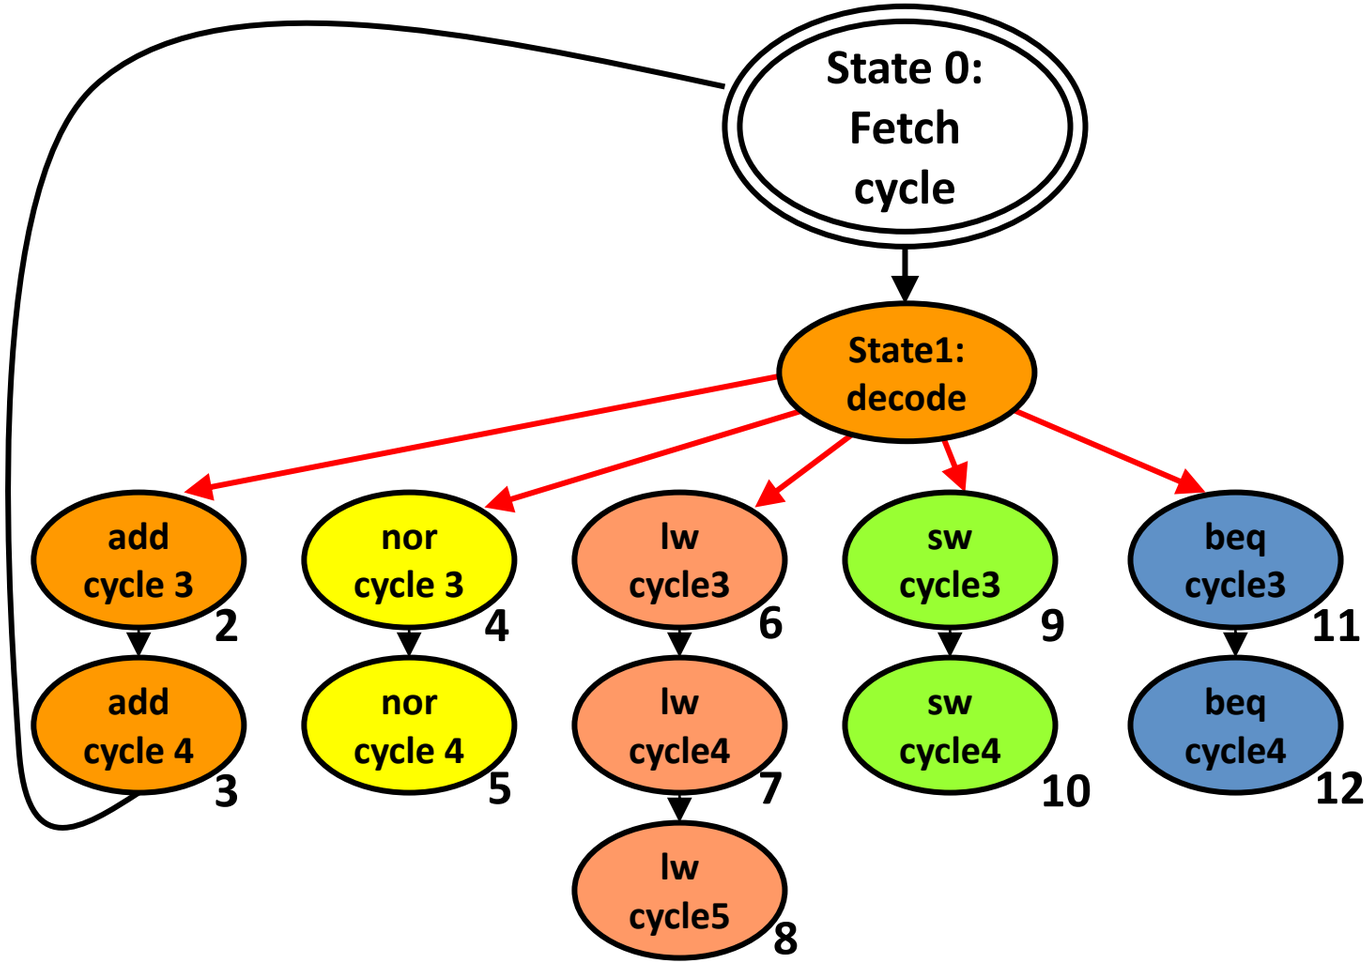
Secondary ROM stores which state we should branch to after decode for each opcode



Control Rom (use of 1111 state)

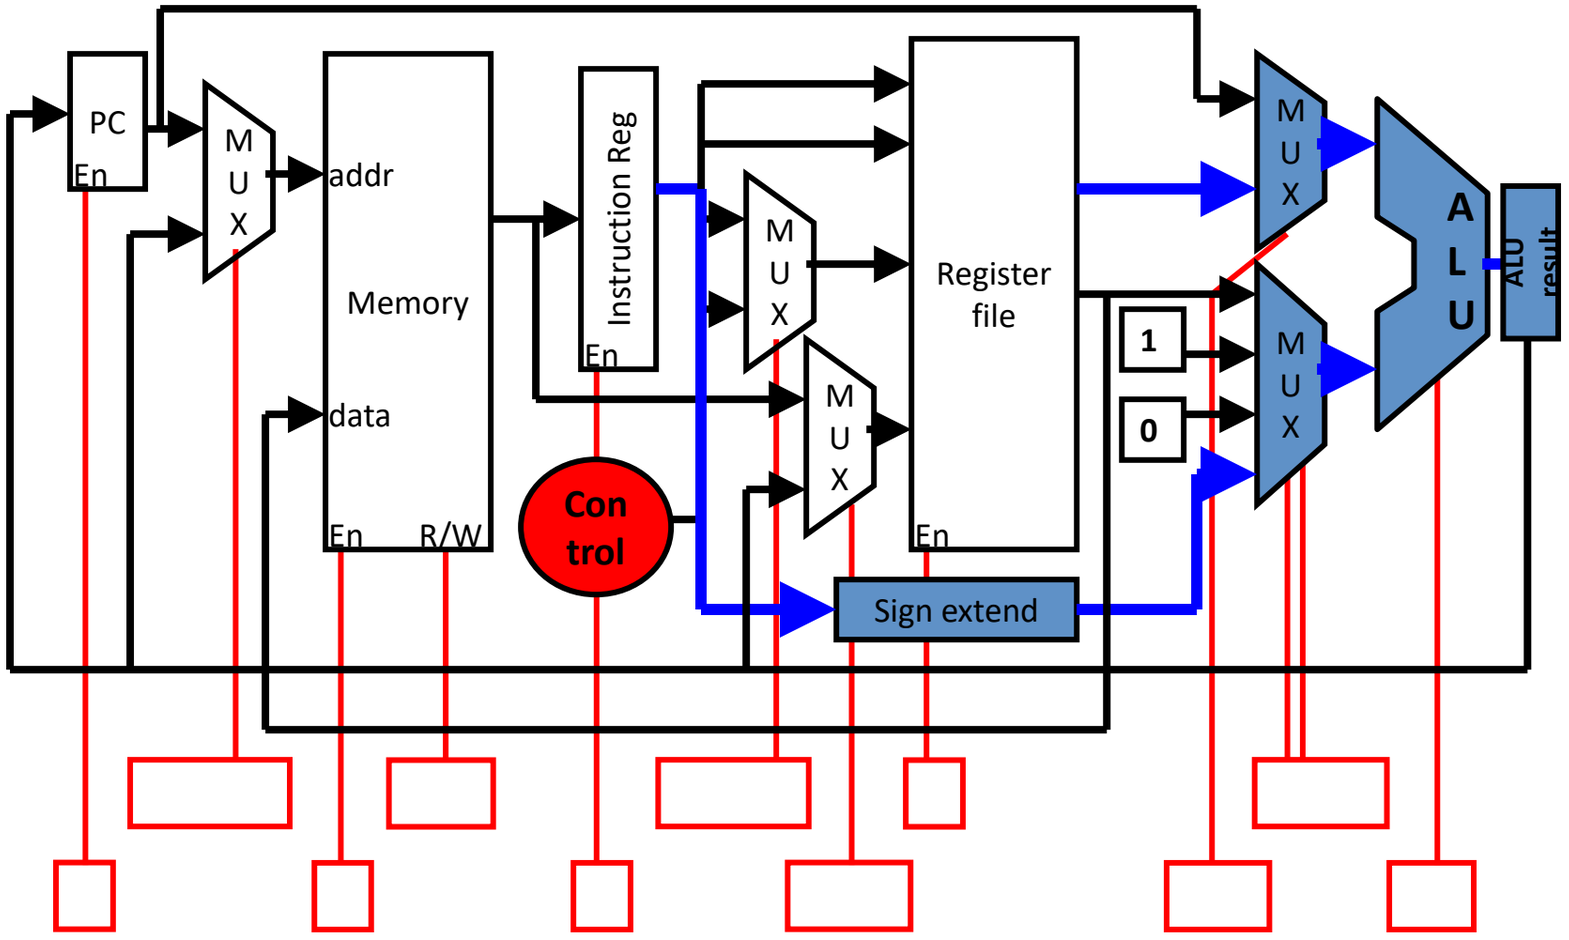


Return to State 0: Fetch cycle to execute the next instruction



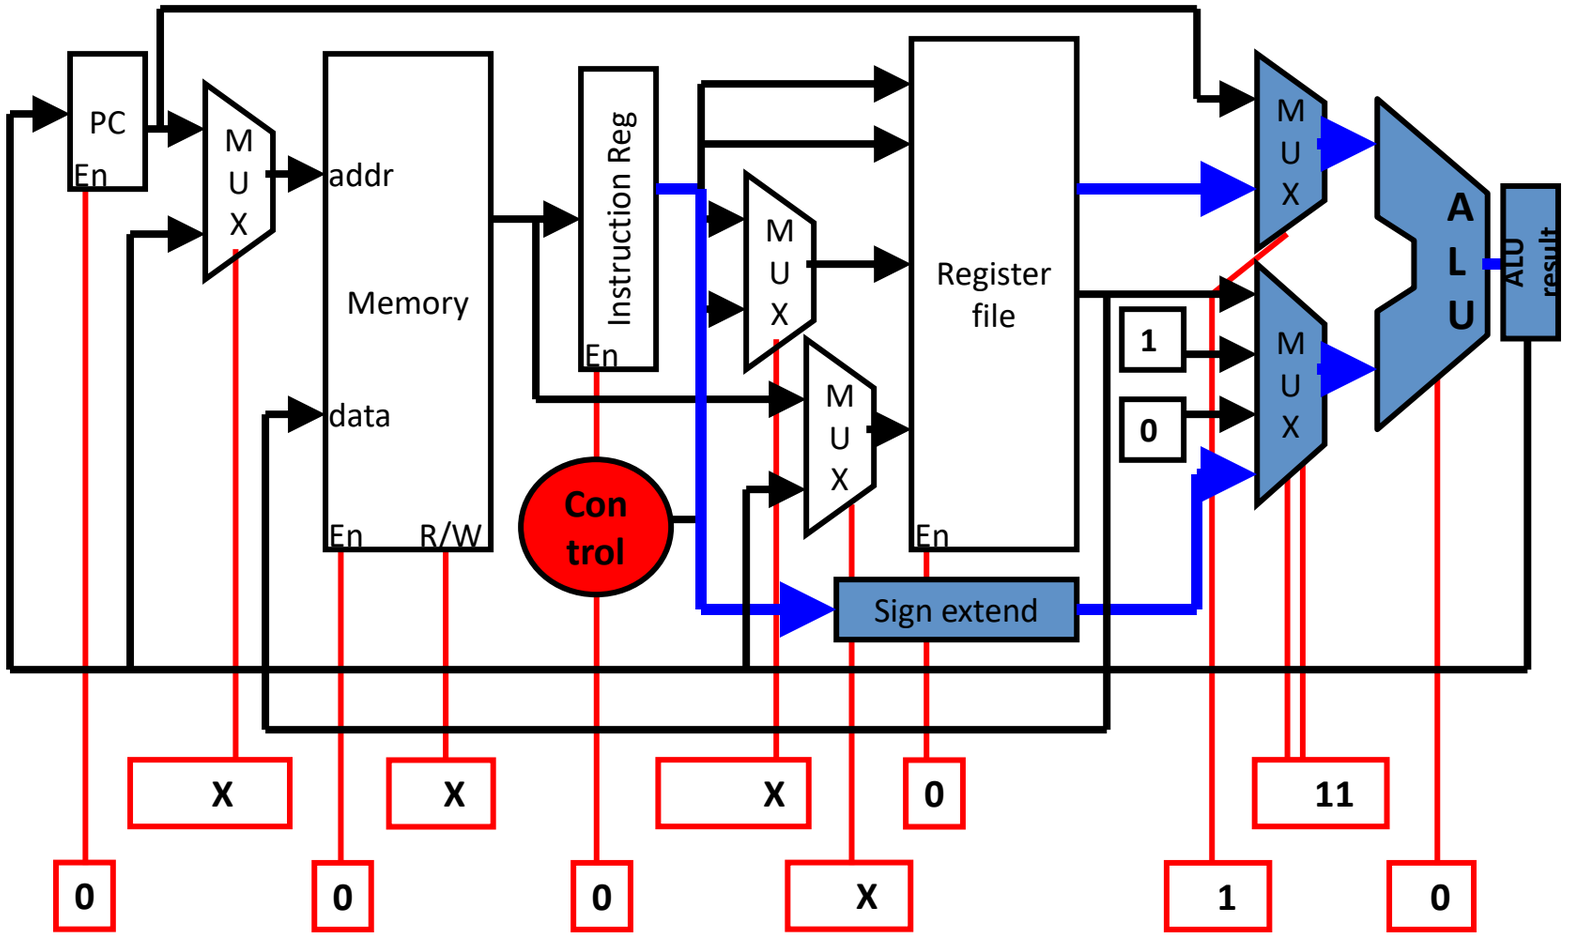
State 6: LW cycle 3

Calculate address for memory reference

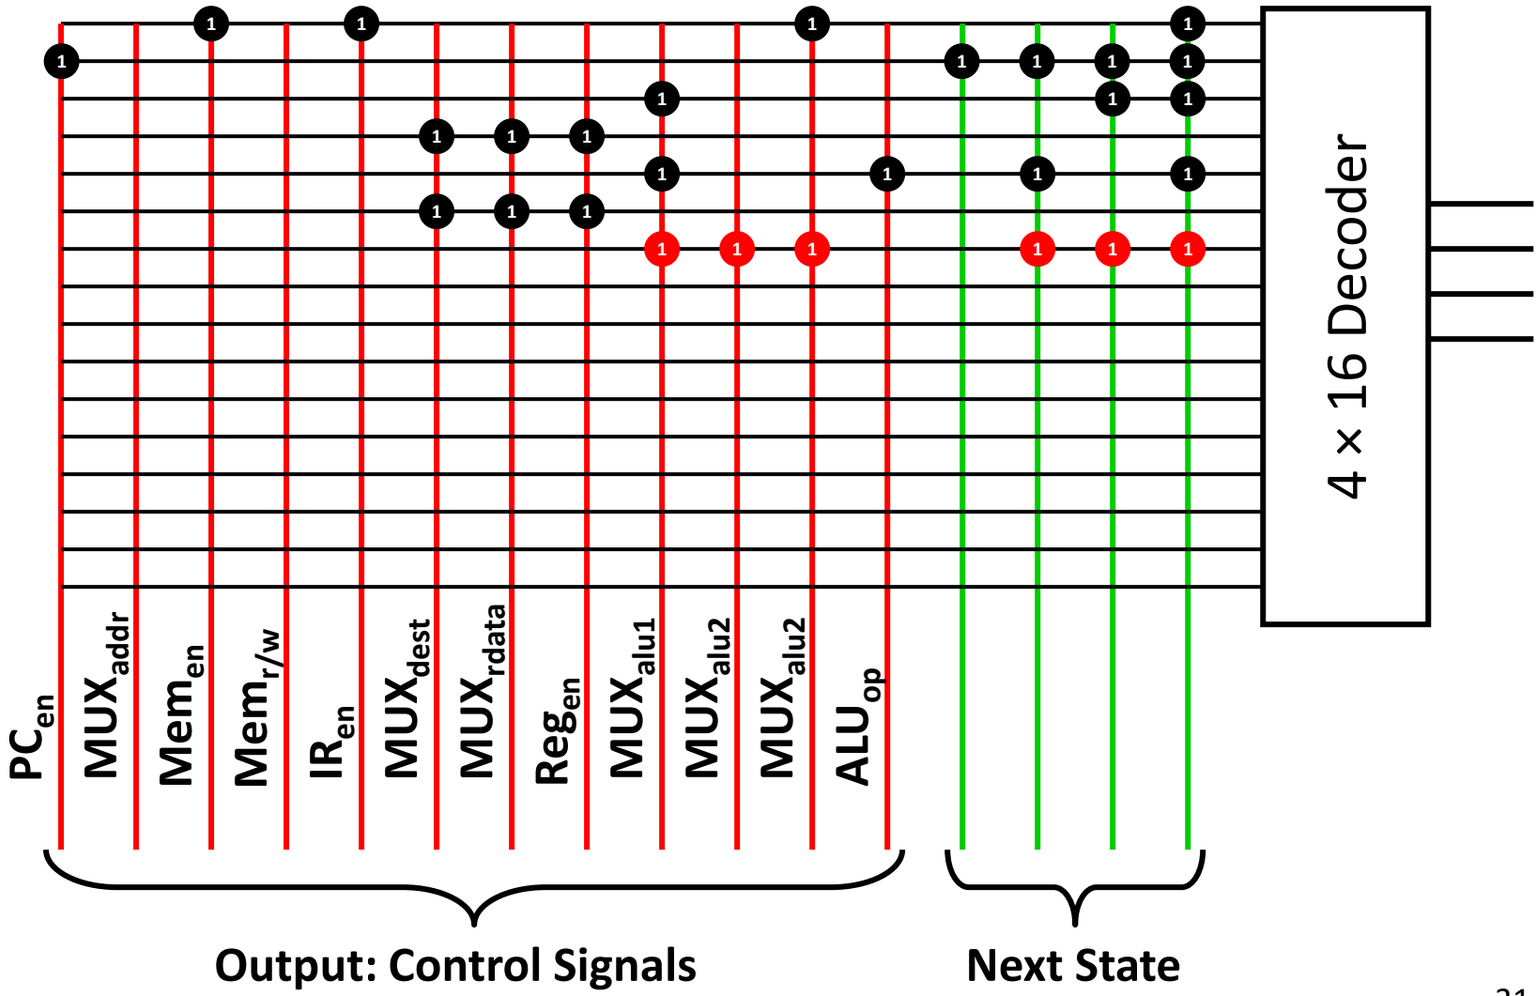


State 6: LW cycle 3

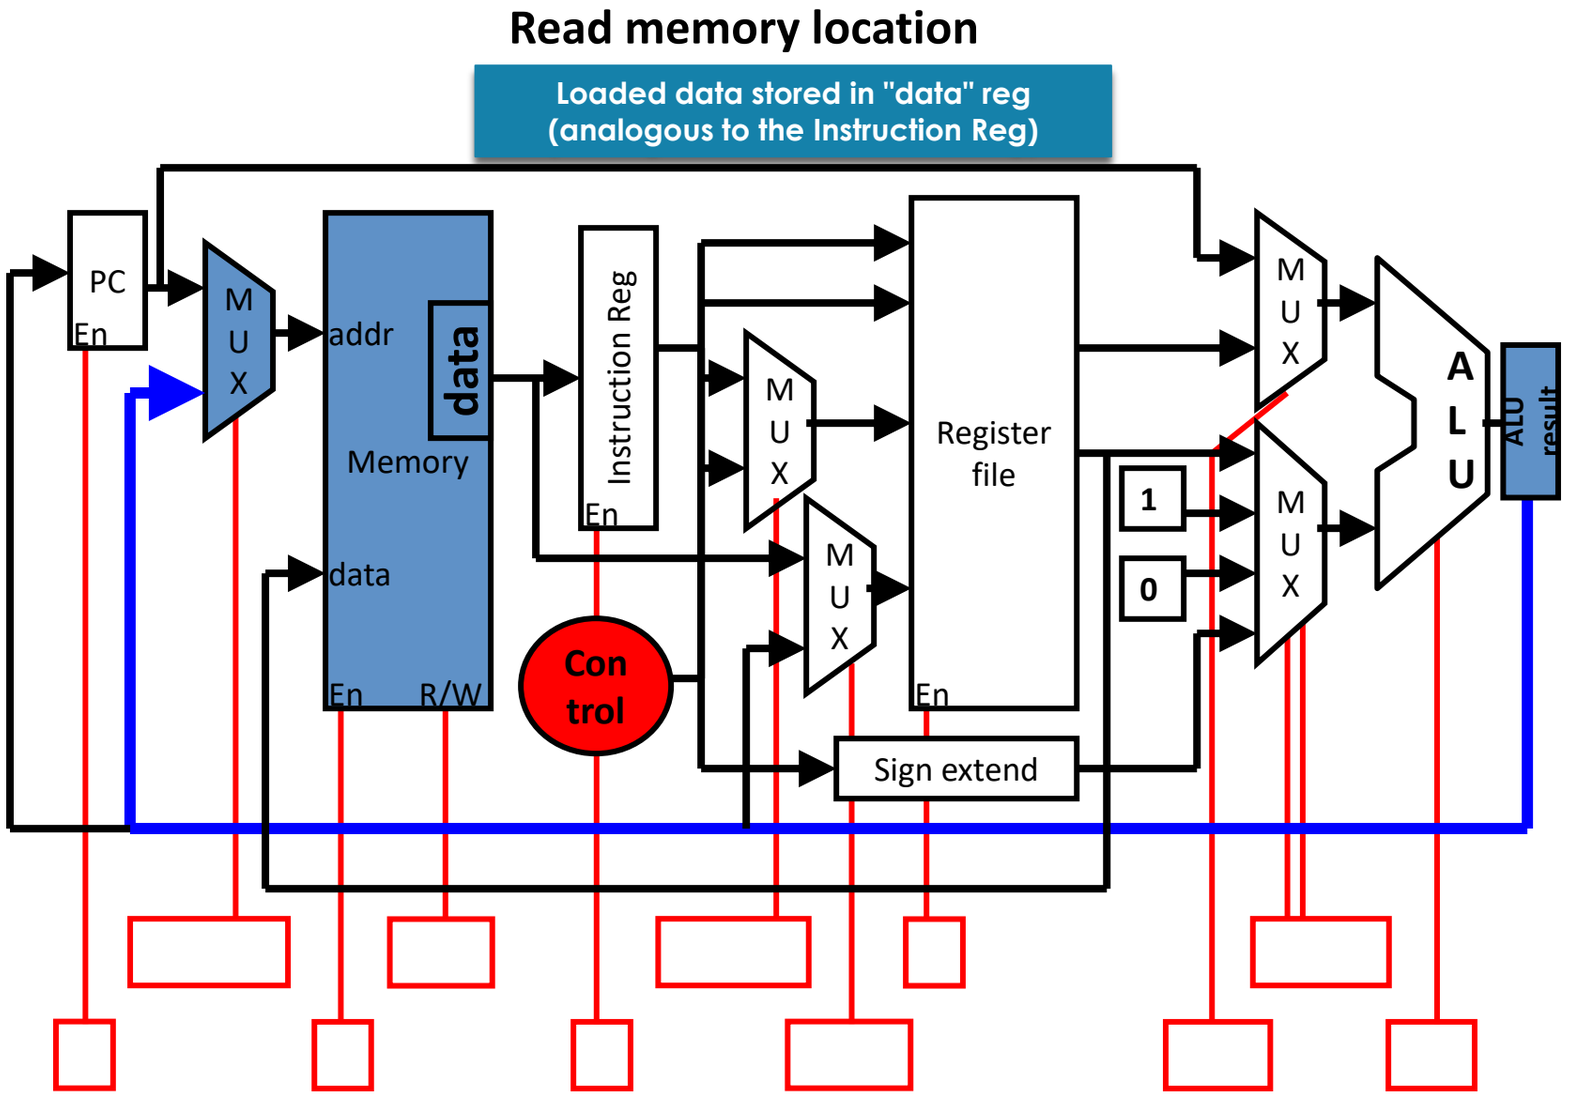
Calculate address for memory reference



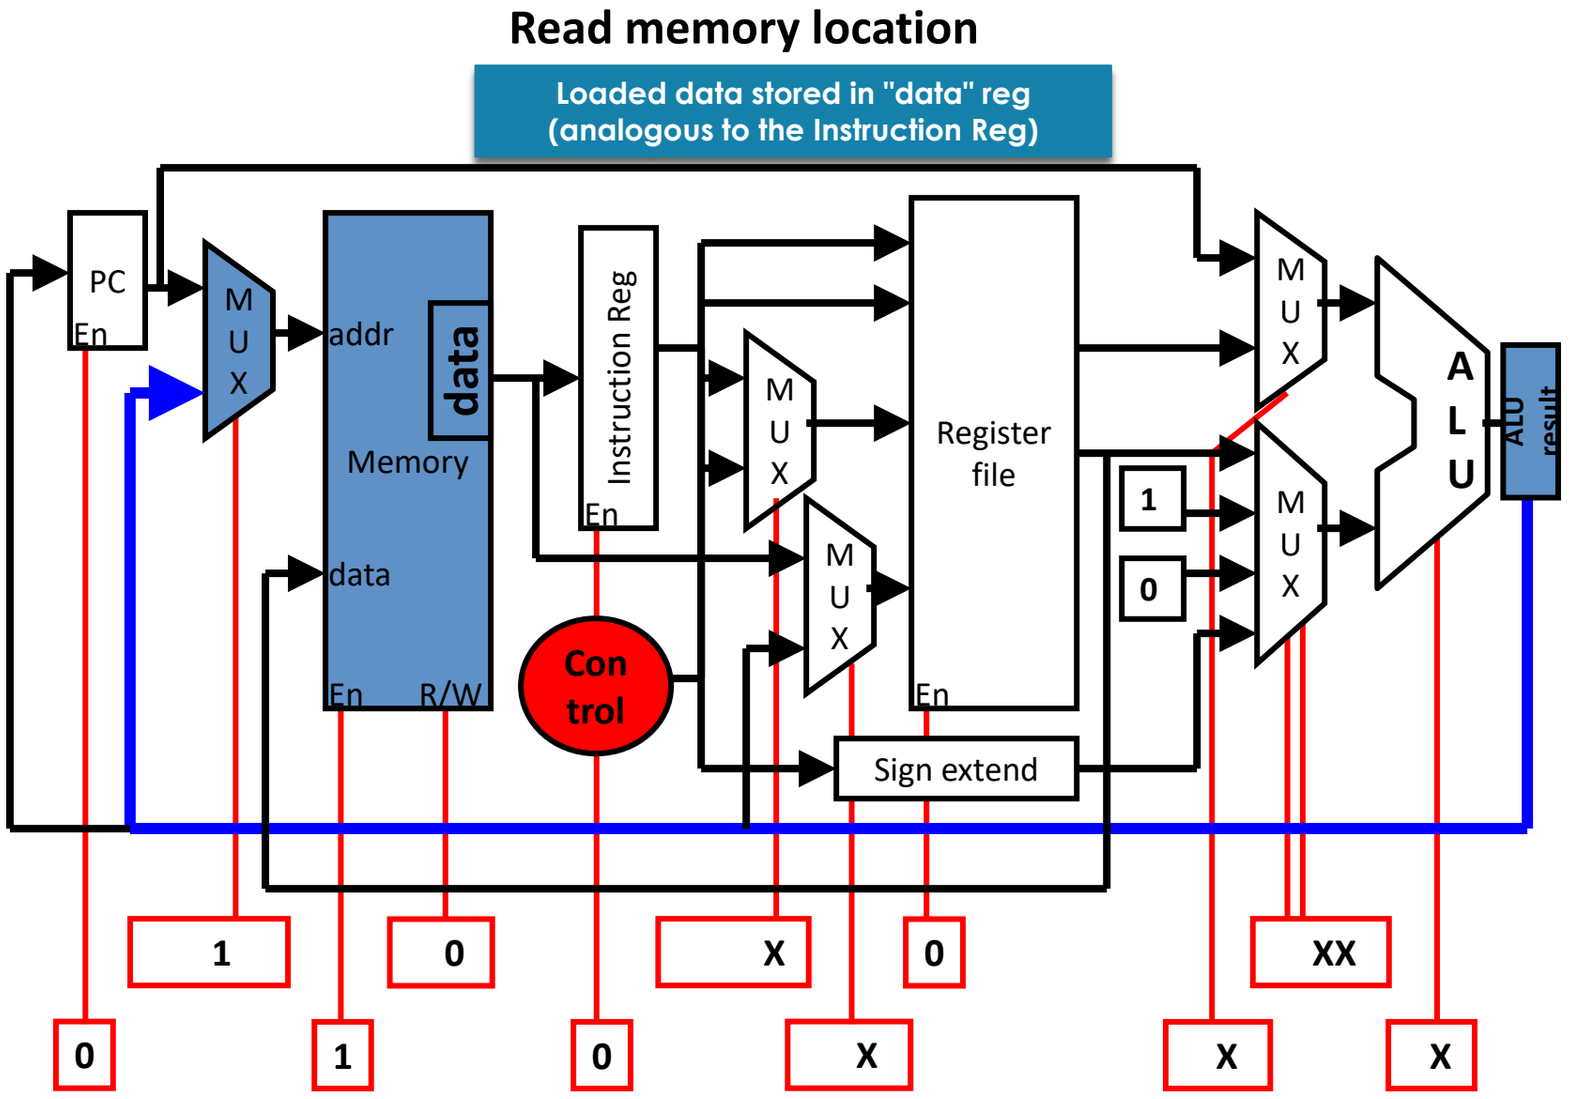
Control Rom (lw cycle 3)



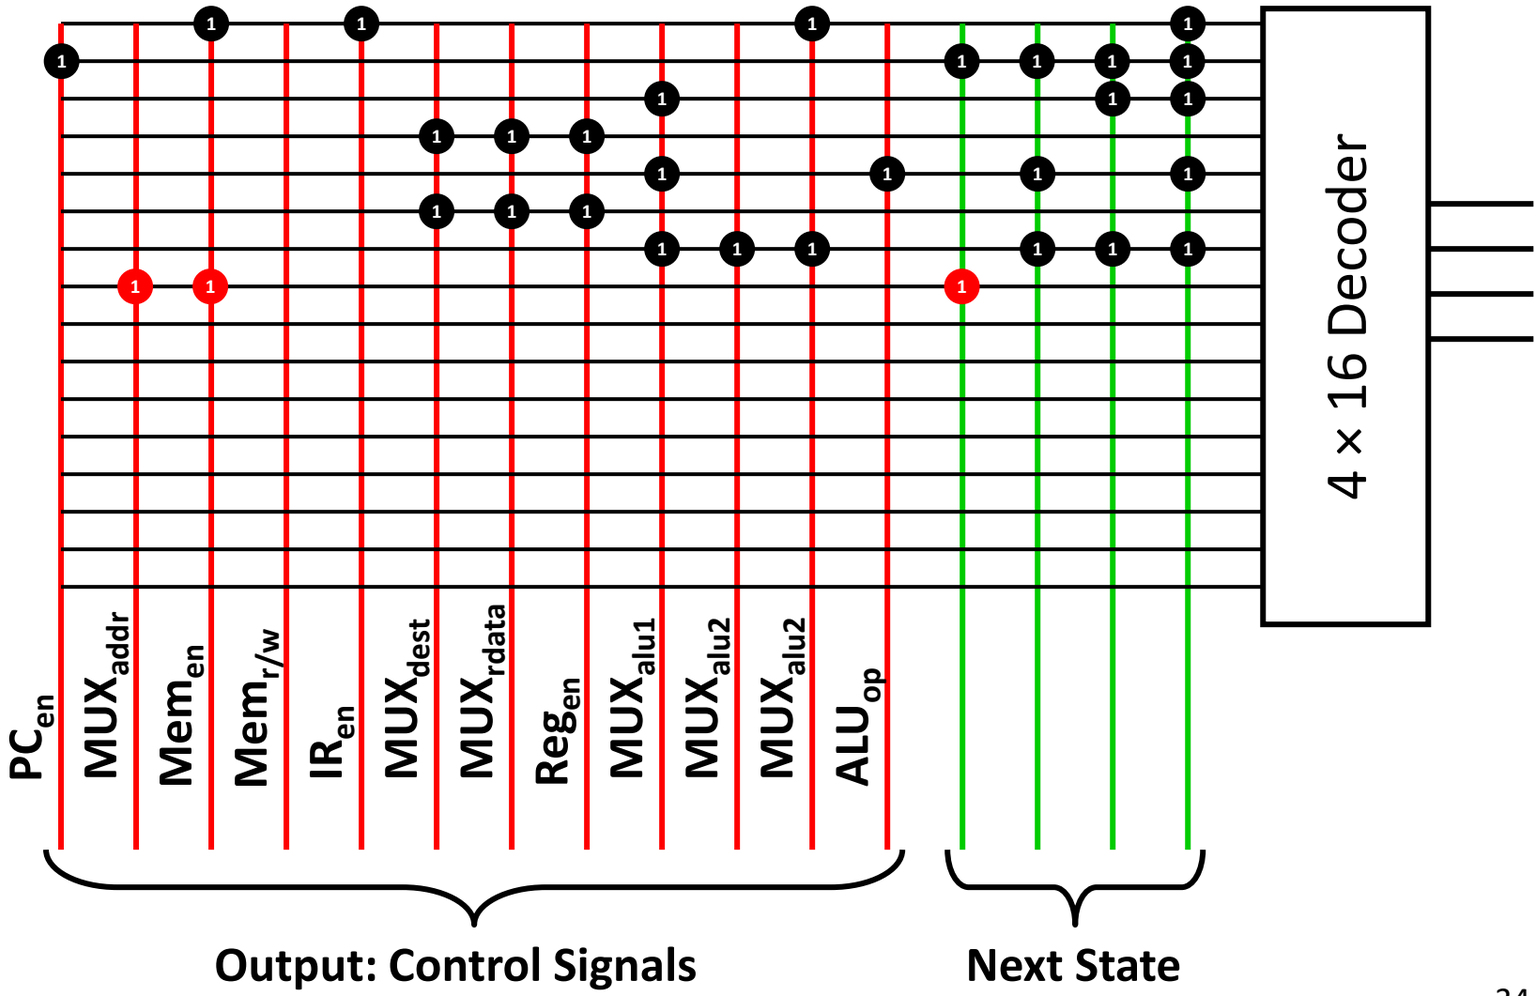
State 7: LW cycle 4



State 7: LW cycle 4

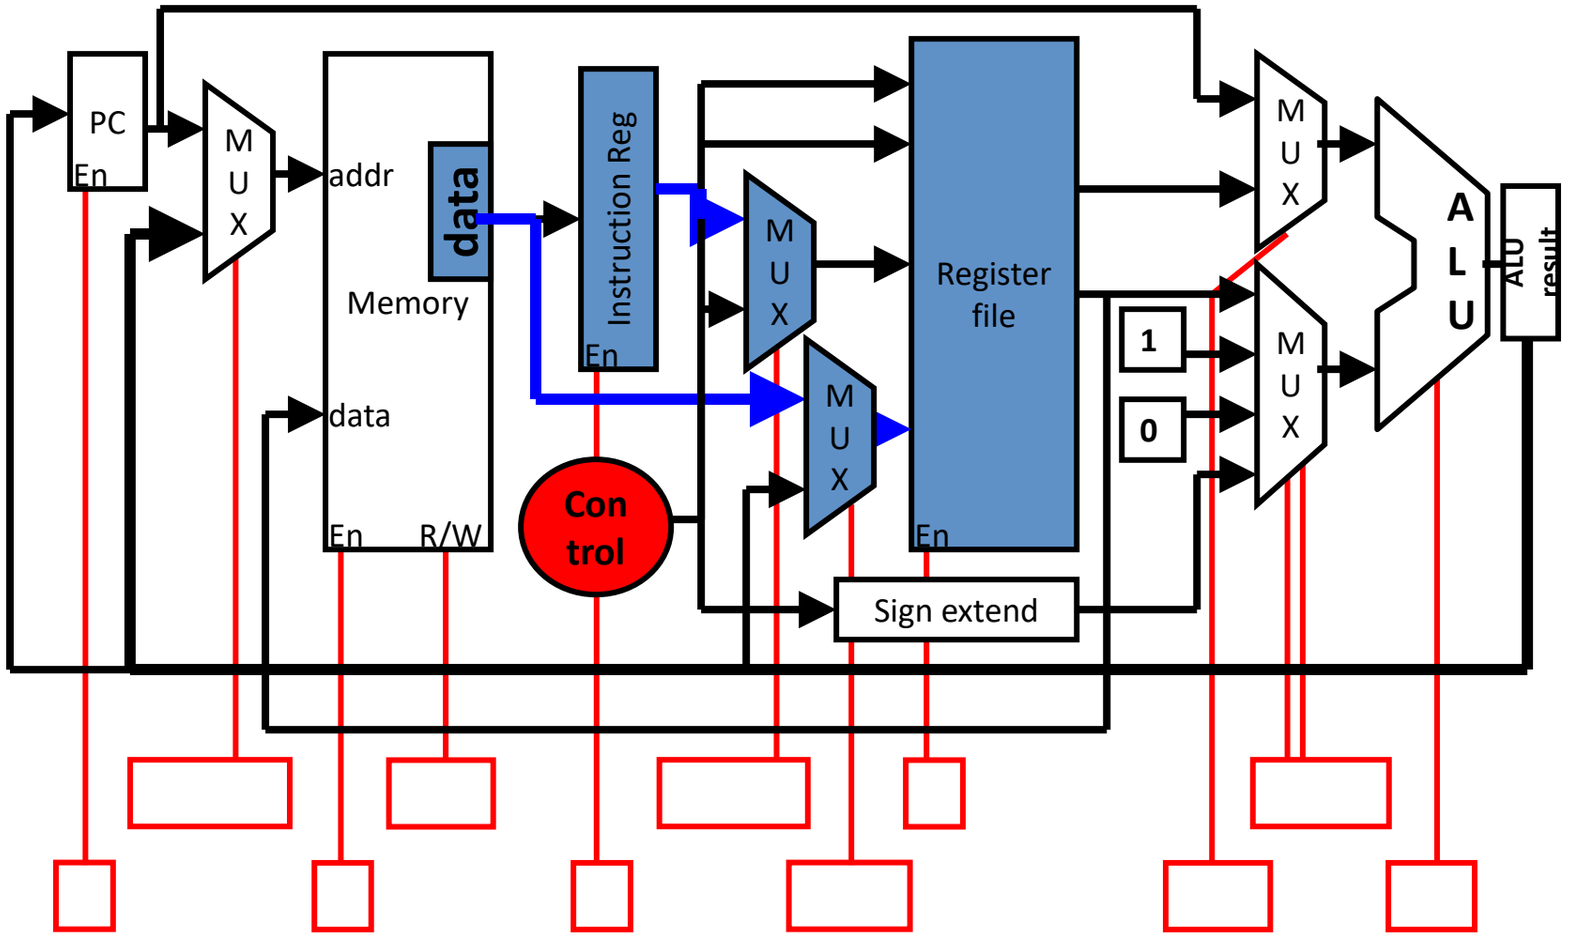


Control Rom (lw cycle 4)



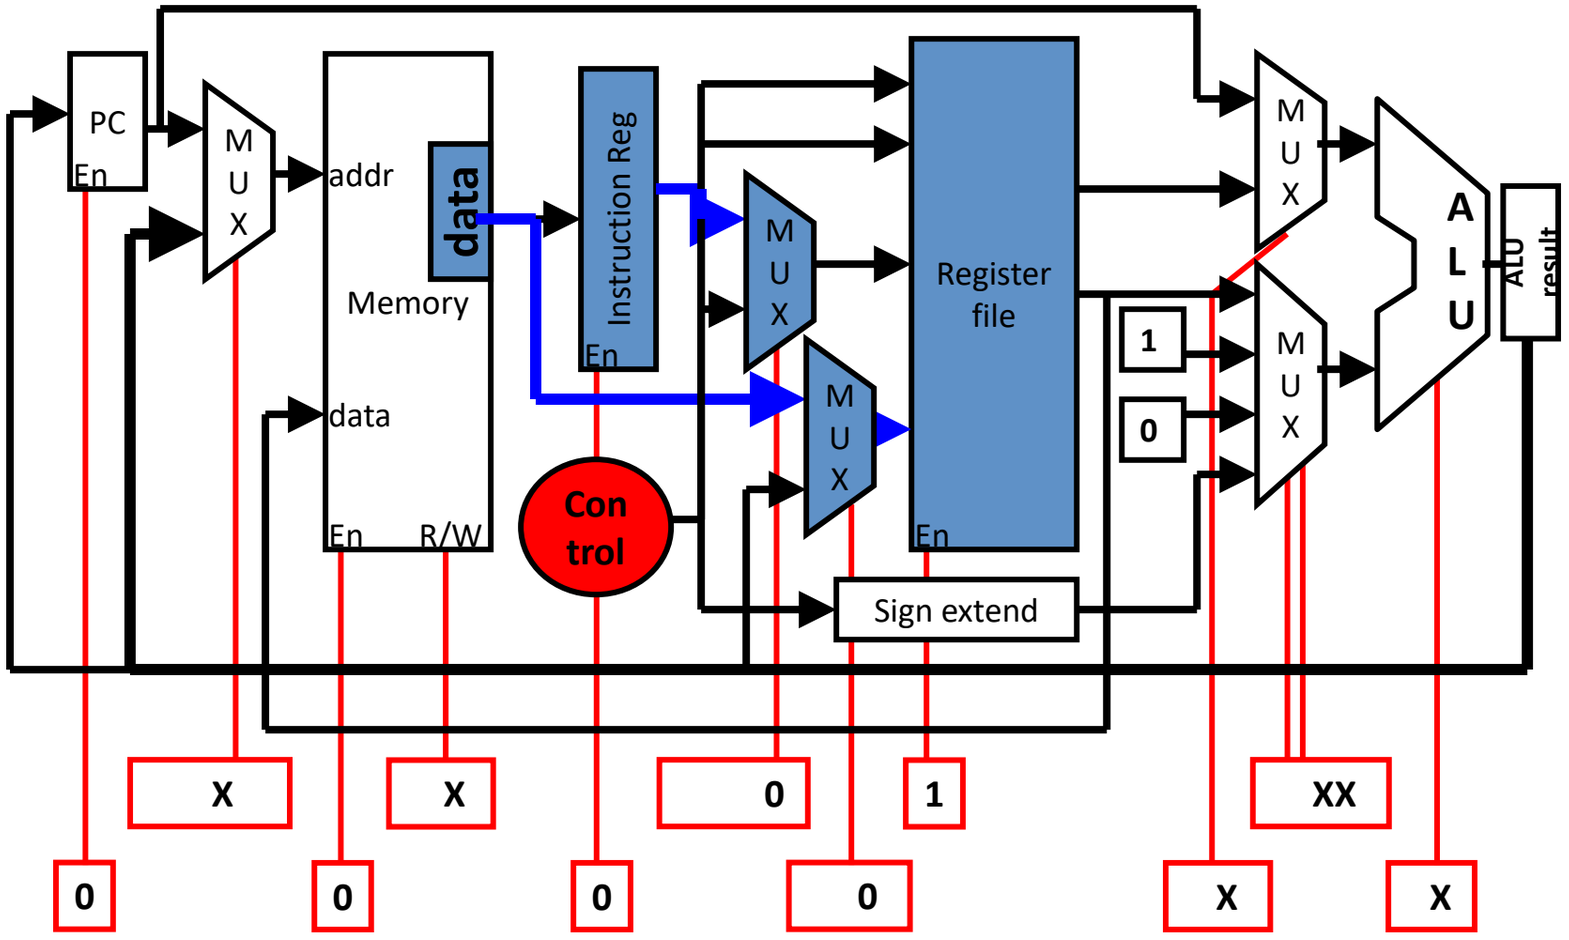
State 8: LW cycle 5

Write memory value to register file

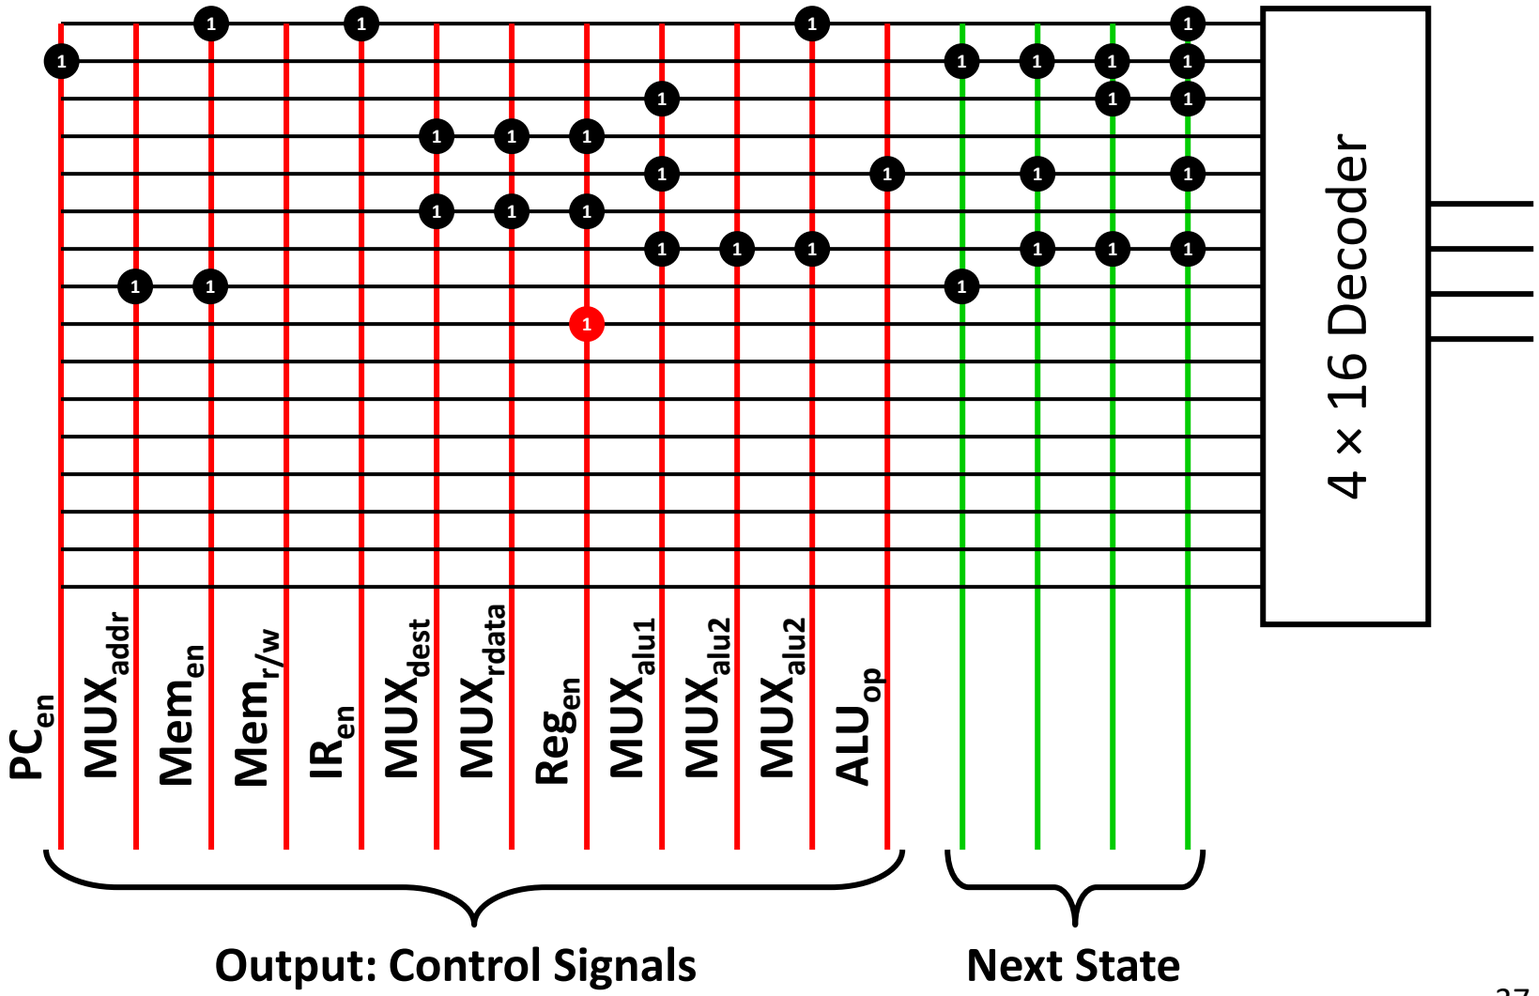


State 8: LW cycle 5

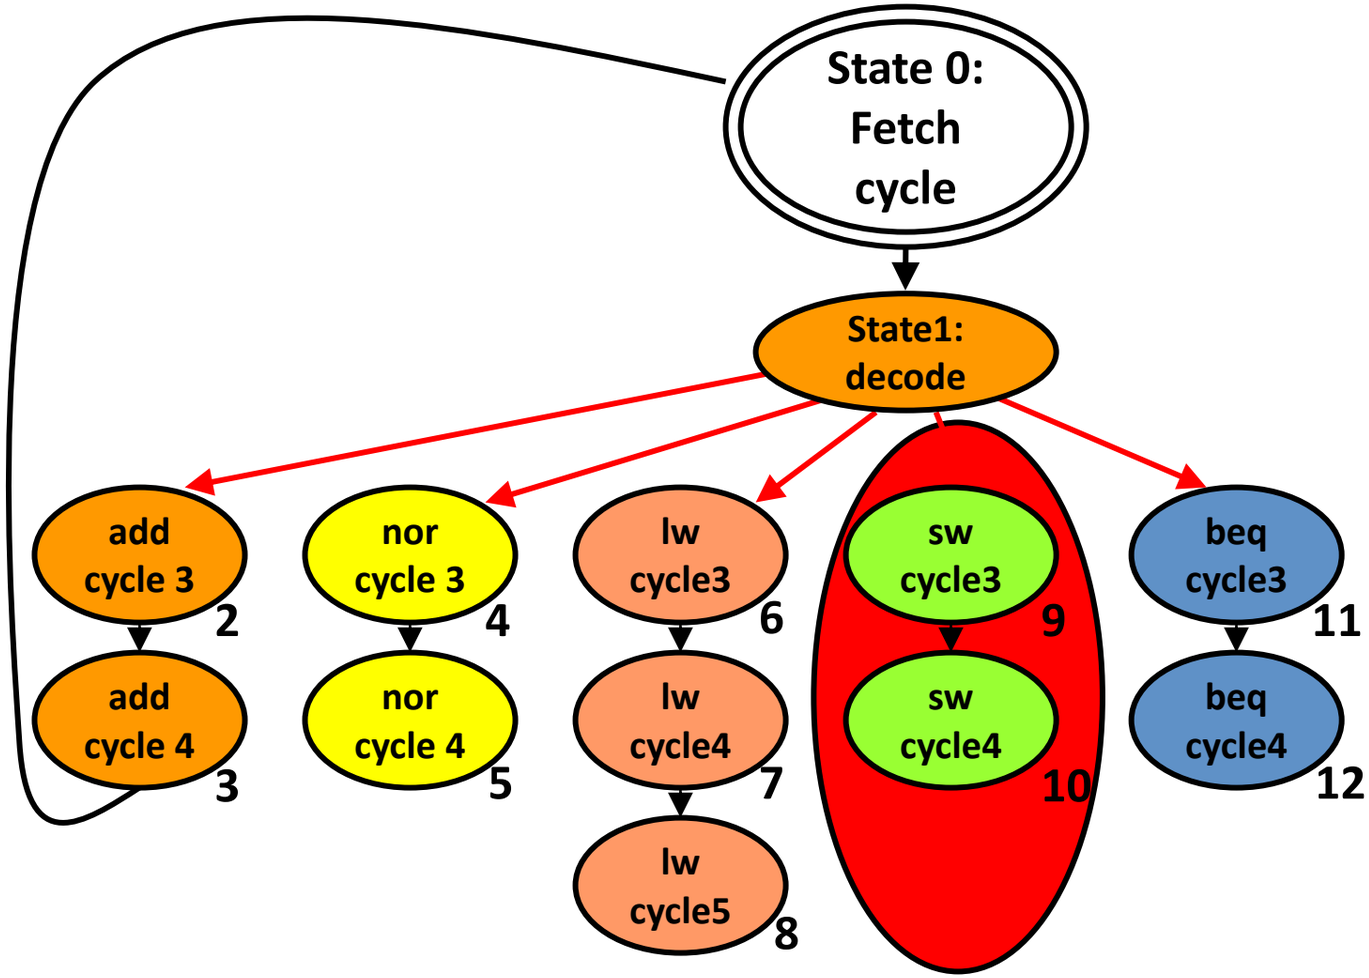
Write memory value to register file



Control Rom (lw cycle 5)

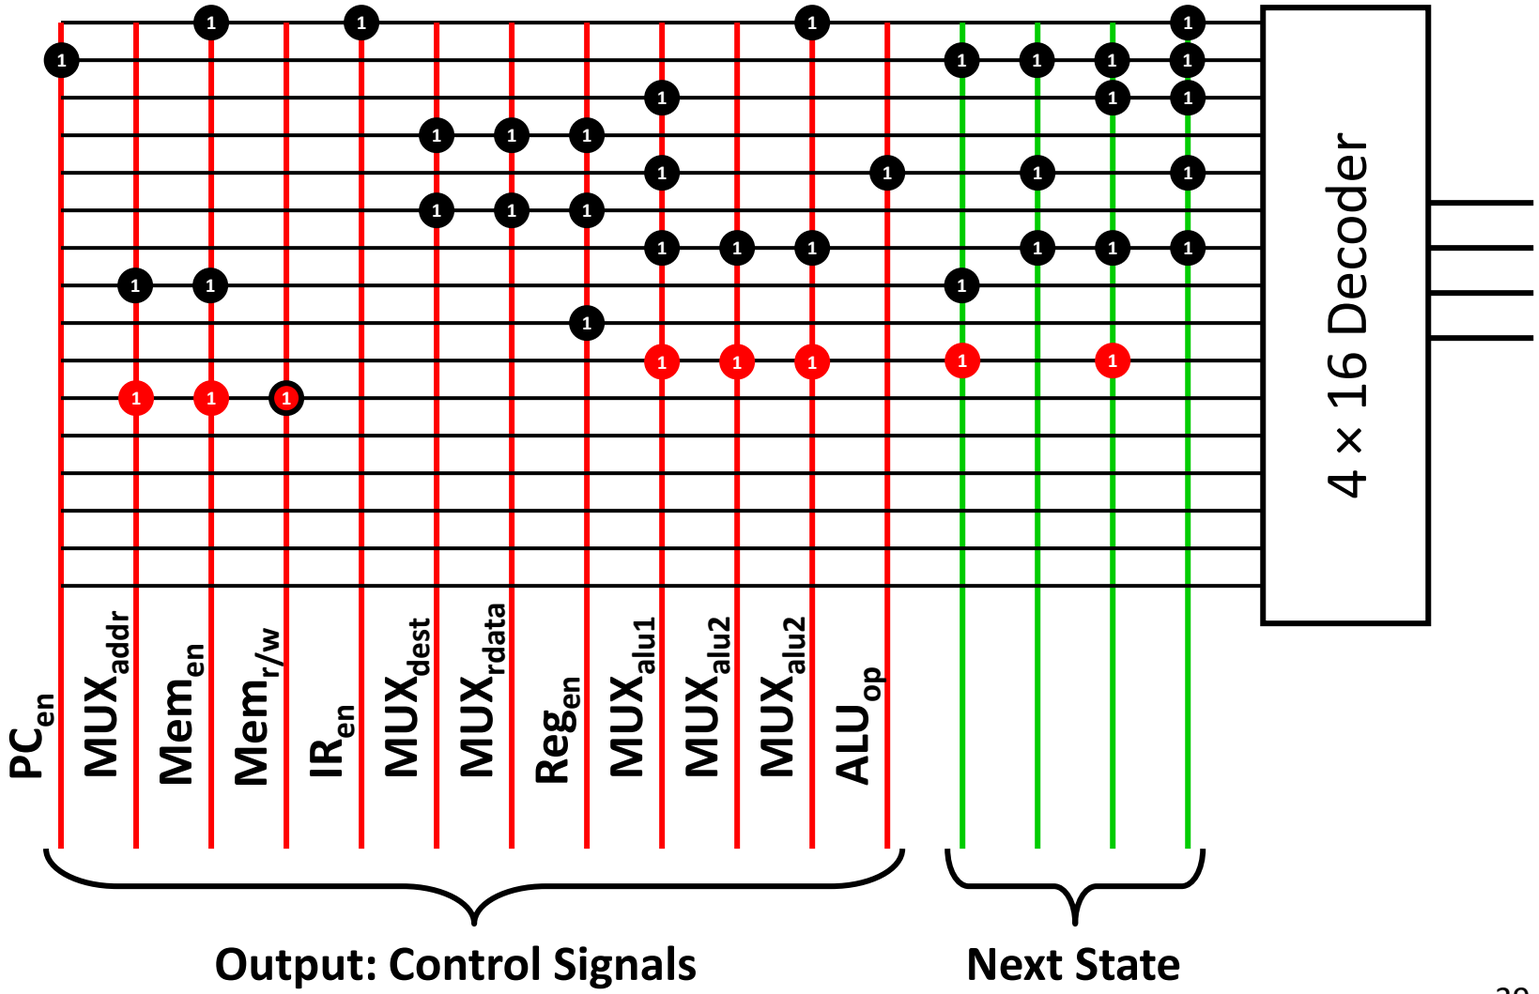


Return to State 0: Fetch cycle to execute the next instruction

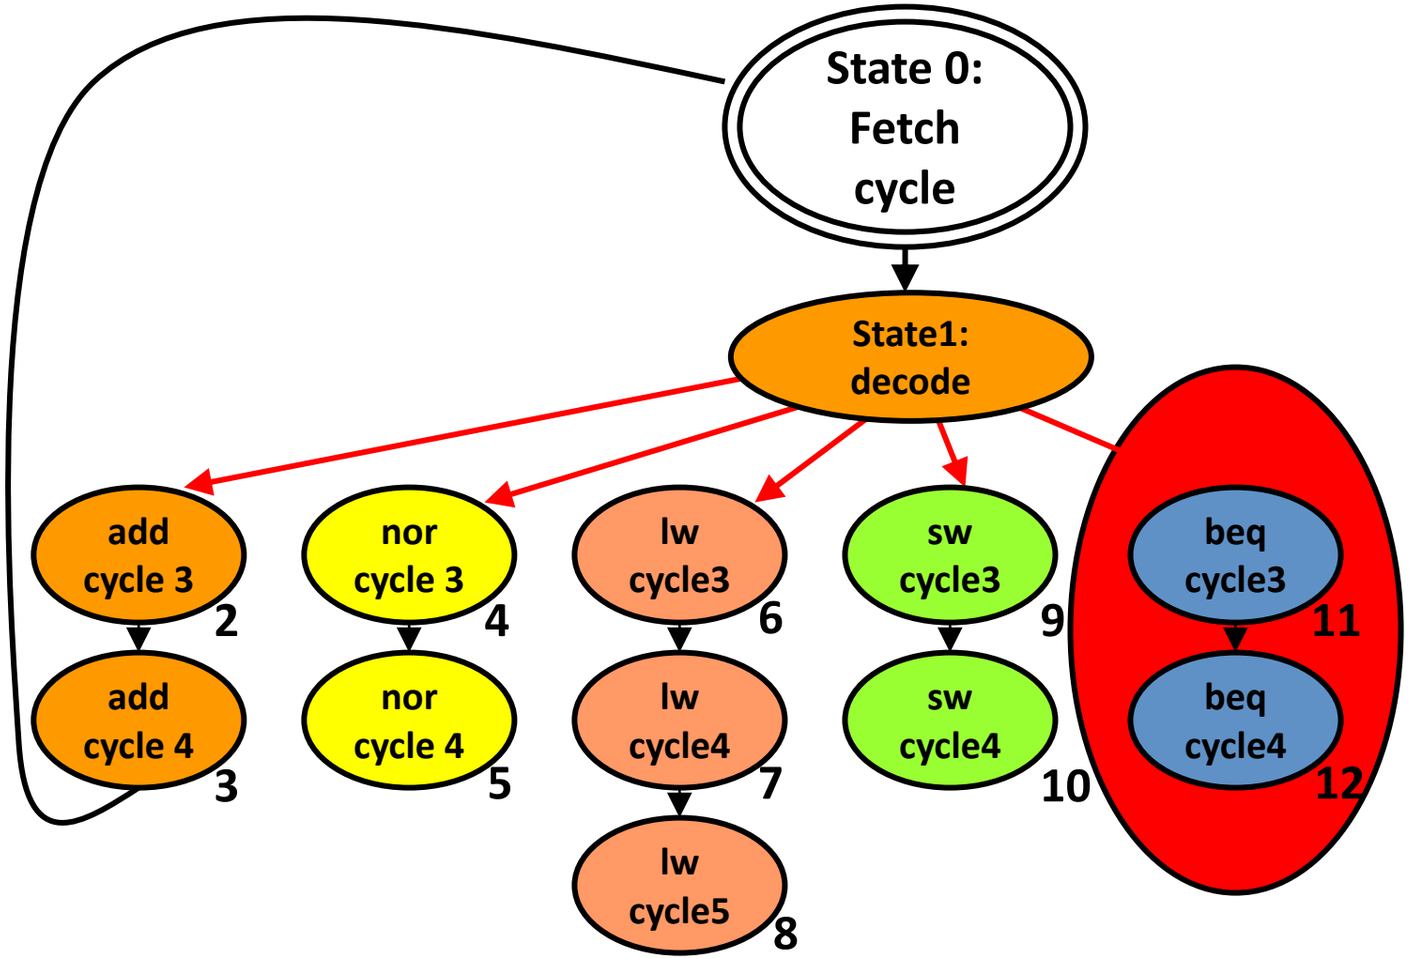


Same as lw, except $Mem_{r/w}$ and Next State

Control Rom (sw cycles 3 and 4)



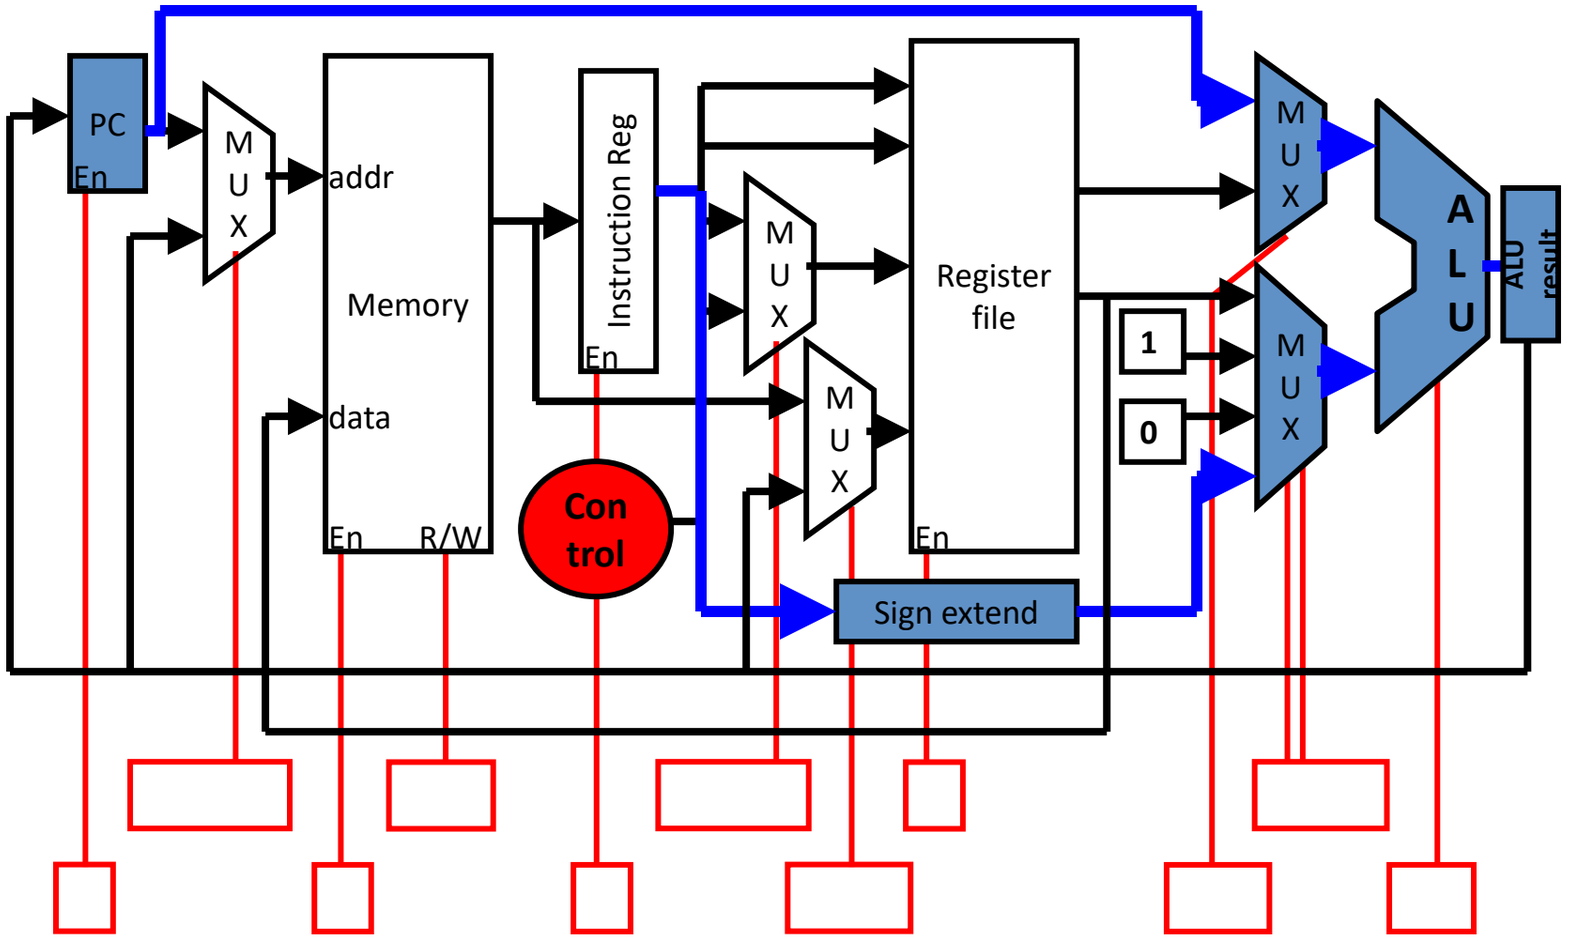
Return to State 0: Fetch cycle to execute the next instruction



State 11: beq cycle 3

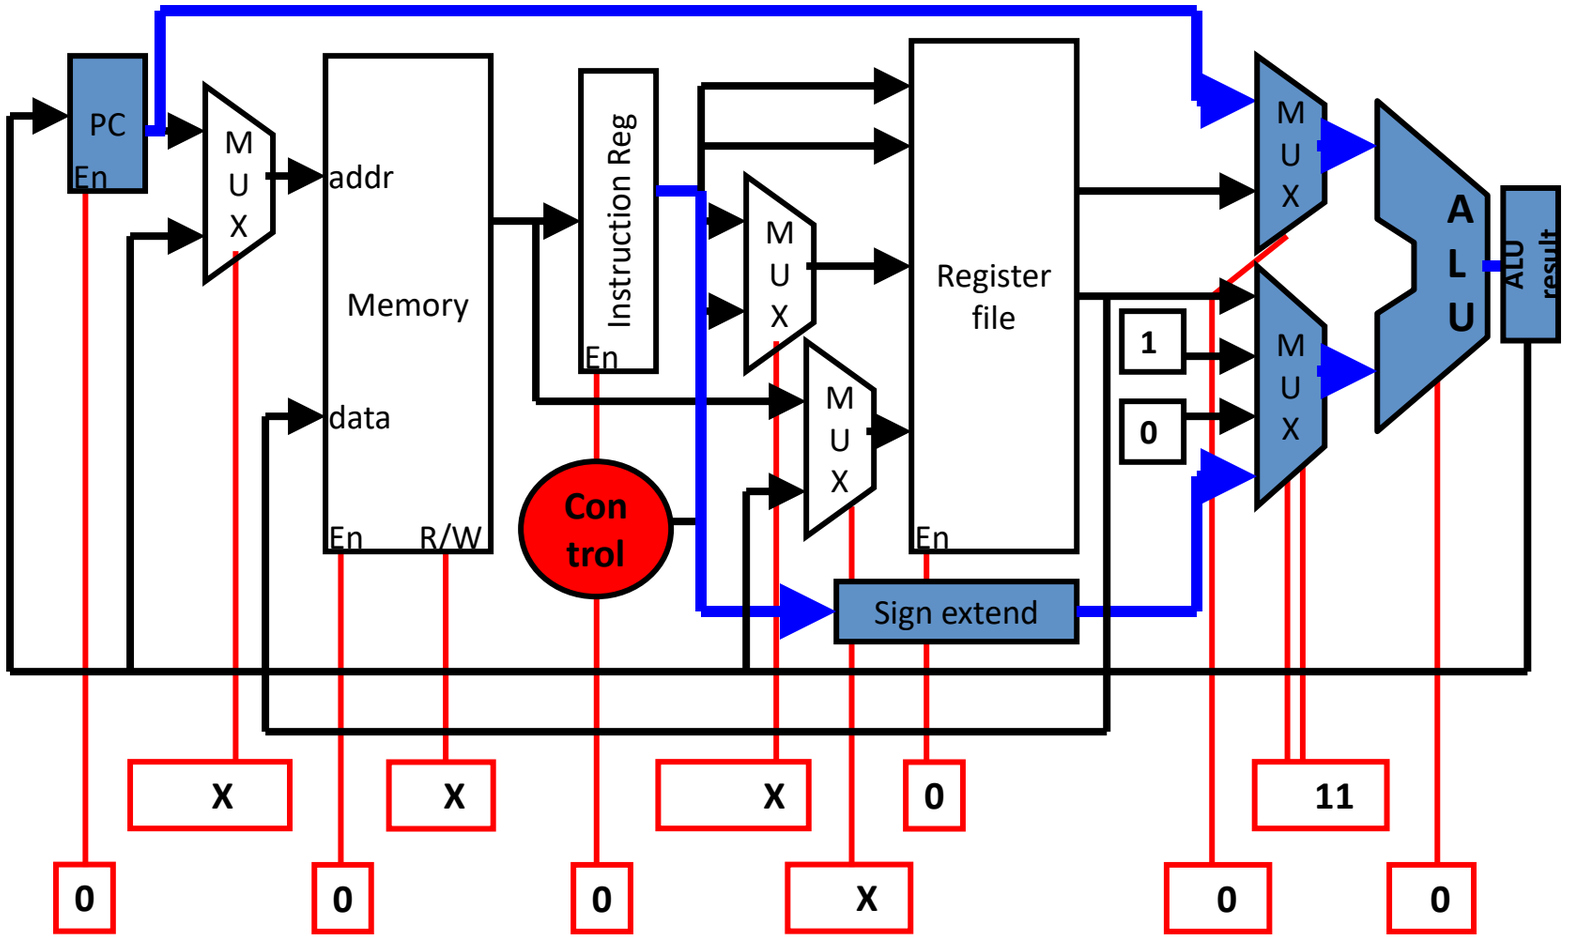
Poll: What will the control bits be?

Calculate target address for branch

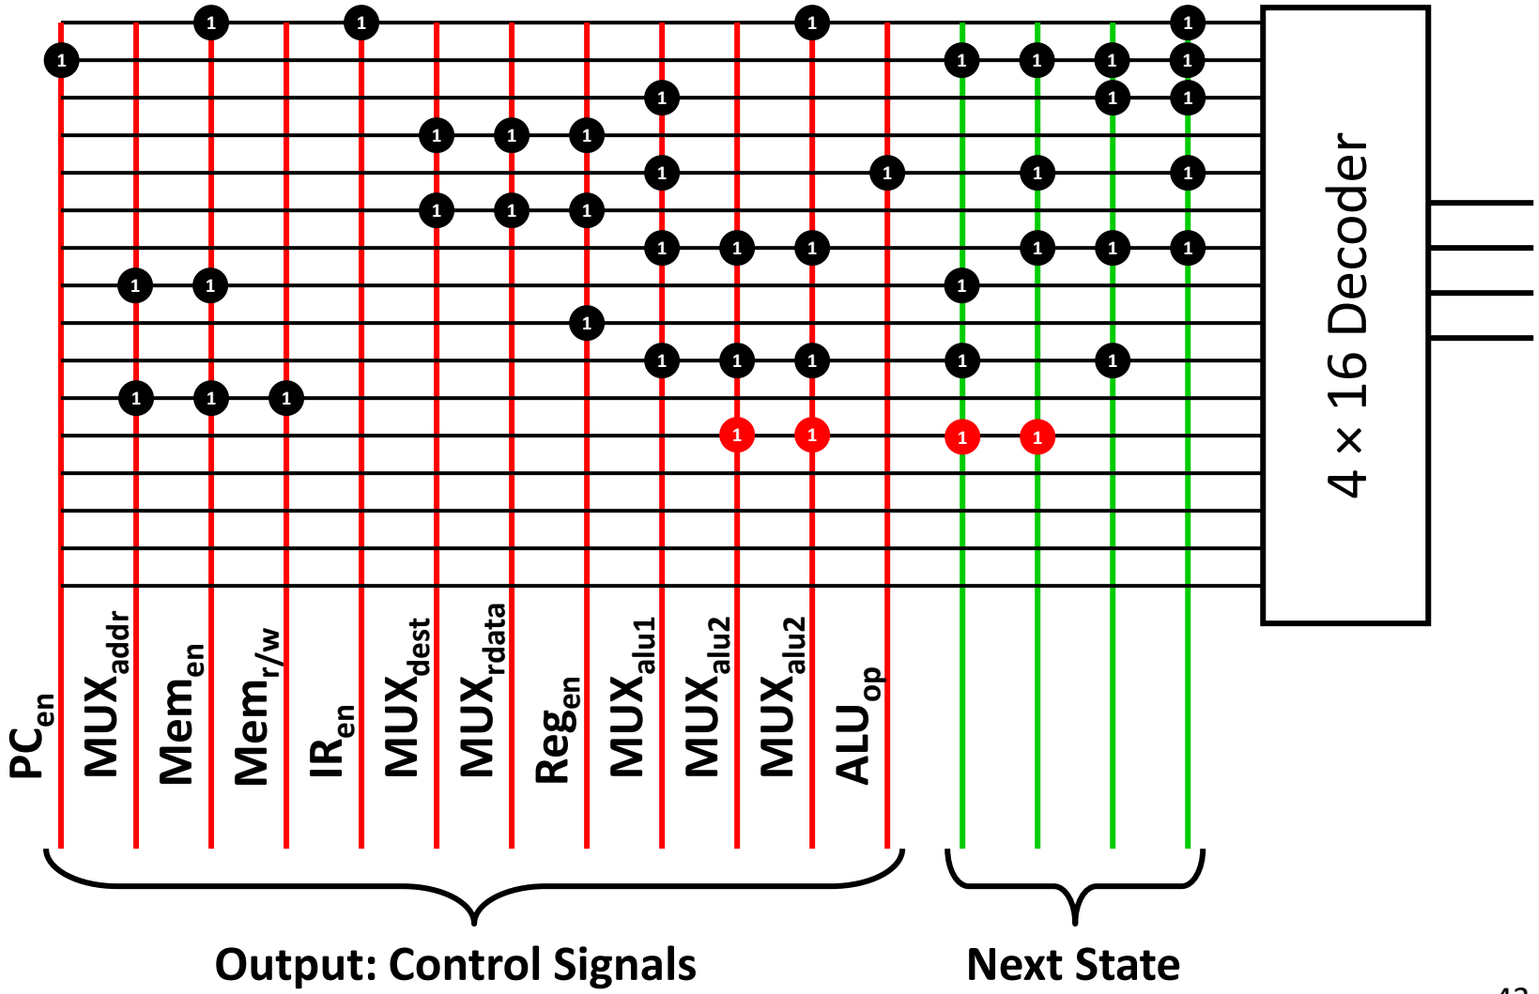


State 11: beq cycle 3

Calculate target address for branch



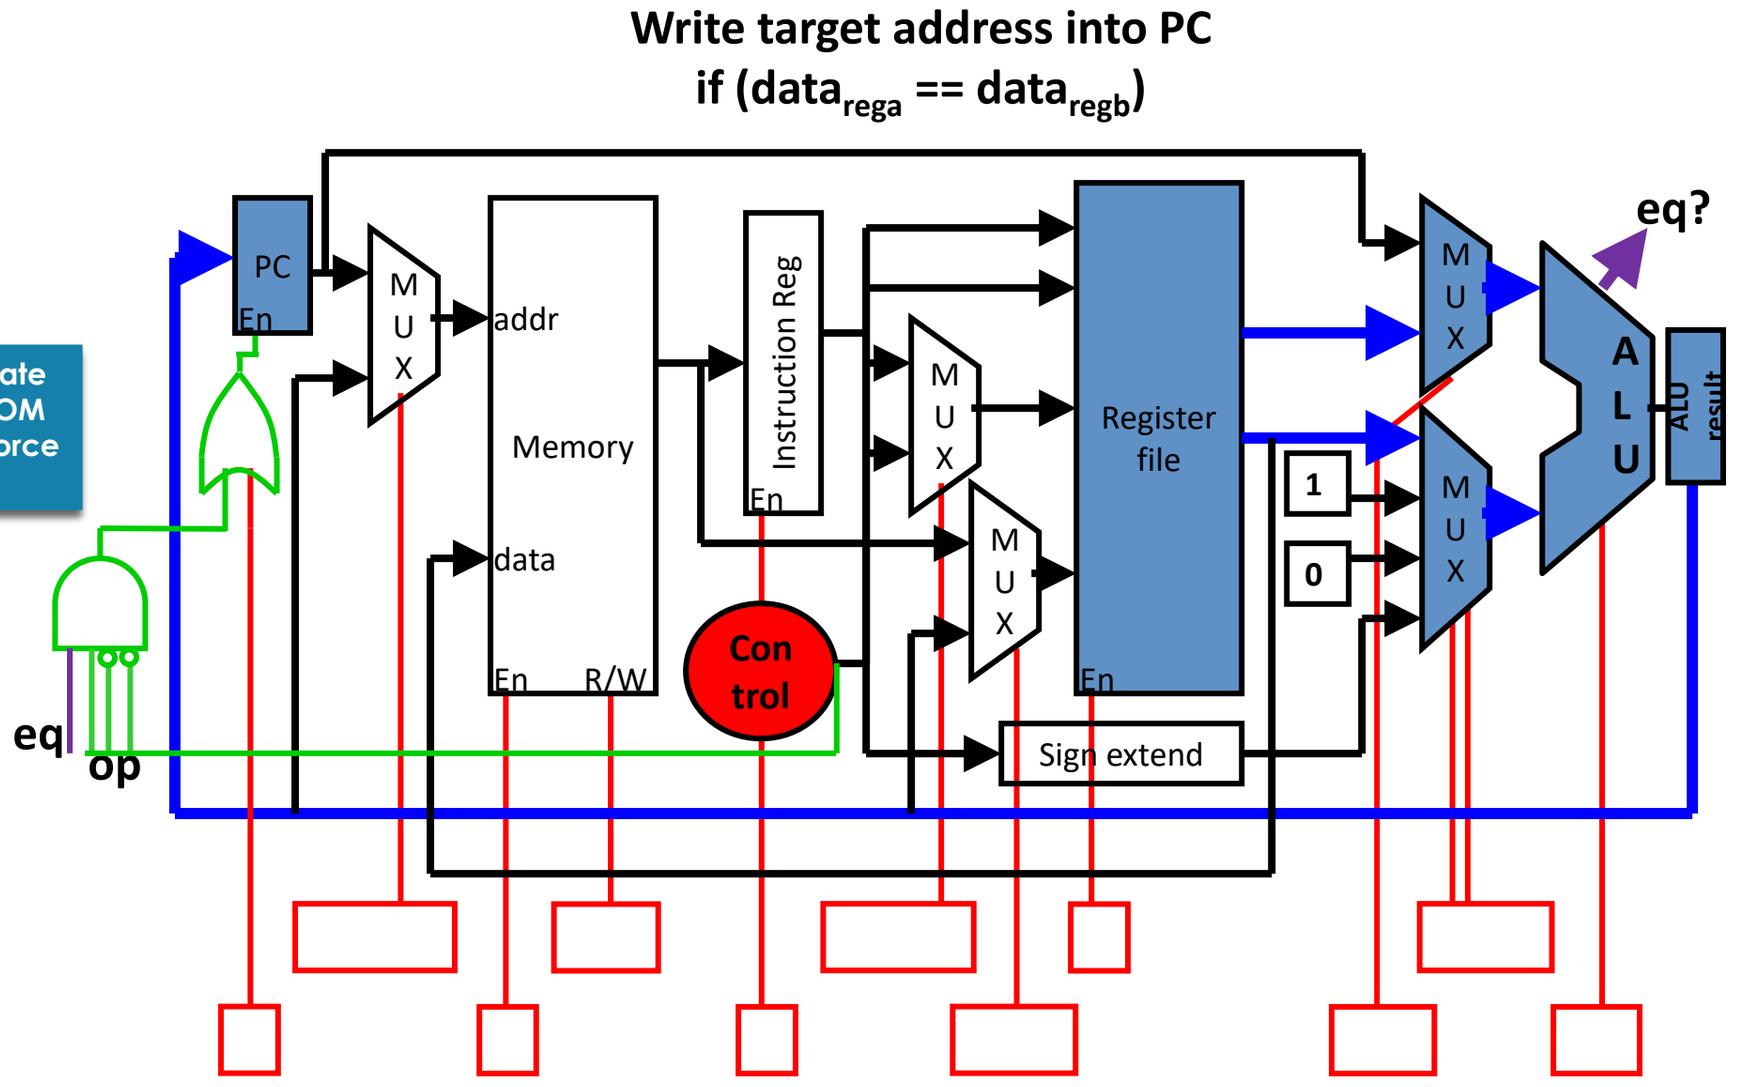
Control Rom (beq cycle 3)



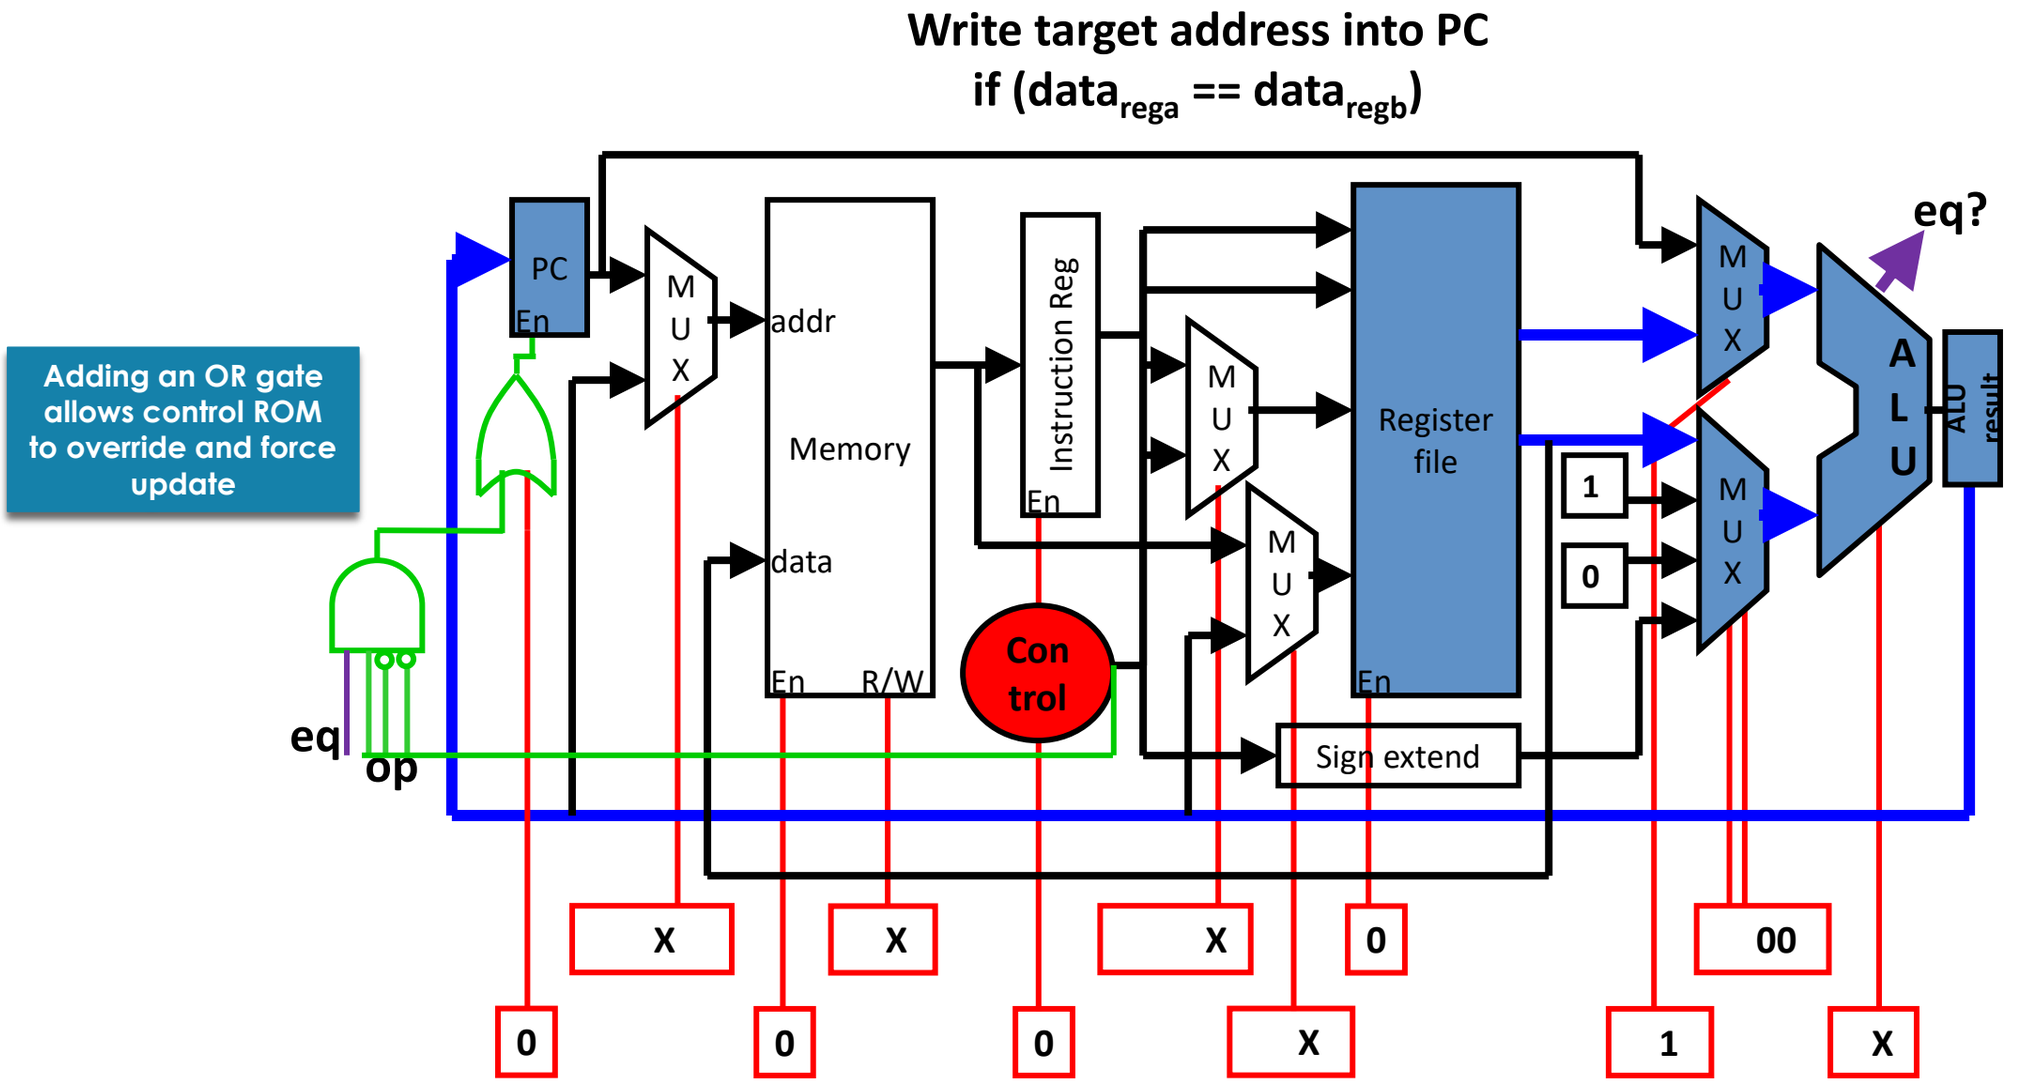
State 12: beq cycle 4

There's a subtle bug here… can you find it?

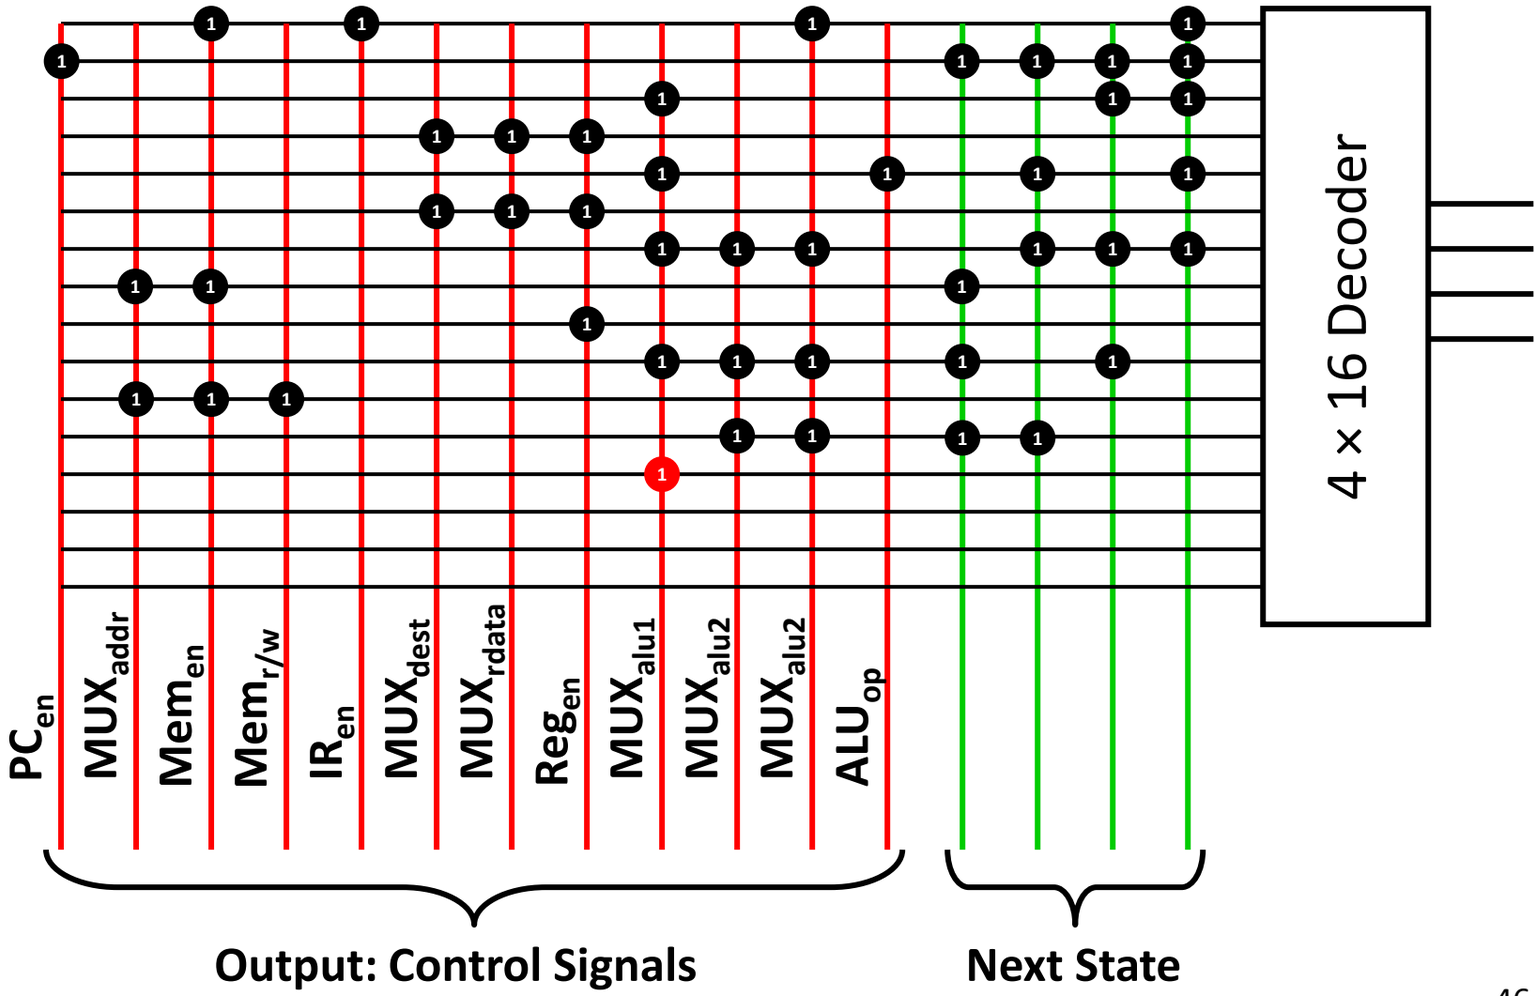
Adding an OR gate allows control ROM to override and force update



State 12: beq cycle 4



Control Rom (beq cycle 4)



Single vs Multi-cycle Performance

1 ns – Register File read/write time

2 ns – ALU/adder

2 ns – memory access

0 ns – MUX, PC access, sign extend, ROM

Poll: How many ns does SC take? MC?

1. Assuming the above delays, what is the best cycle time that the LC2k multi-cycle datapath could achieve? Single cycle?

2. Assuming the above delays, for a program consisting of 25 LW, 10 SW, 45 ADD, and 20 BEQ, which is faster?

Single vs Multi-cycle Performance

1 ns – Register File read/write time

2 ns – ALU/adder

2 ns – memory access

0 ns – MUX, PC access, sign extend, ROM

1. Assuming the above delays, what is the best cycle time that the LC2k multi-cycle datapath could achieve? Single cycle?

   MC: MAX(2, 1, 2, 2, 1) = 2ns

   SC: 2 + 1 + 2 + 2 + 1 = 8 ns

2. Assuming the above delays, for a program consisting of 25 LW, 10 SW, 45 ADD, and 20 BEQ, which is faster?

   SC: 100 cycles * 8 ns = 800 ns

   MC: (25*5 + 10*4 + 45*4 + 20*4)cycles * 2ns = 850 ns

Single and Multi-cycle performance

- Wait, multi-cycle is worse??
- For our ISA, most instructions take about the same time
- Multi-cycle shines when some instructions take much longer
- E.g. if we add a long latency instruction like multiply:
  - Let's say operation takes 10 ns, but could be split into 5 stages of 2 ns
  - SC: clock period = 16 ns, performance is 1600 ns
  - MC: clock period = 2 ns, performance is 850 ns

Performance Metrics – Execution time

- What we really care about in a program is **execution time**
  - **Execution time** = total instructions executed X CPI x clock period
  - The "Iron Law" of performance
- CPI = **average** number of clock **cycles per instruction** *for an application*
- To calculate multi-cycle CPI we need:
  - Cycles necessary for each type of instruction
  - Mix of instructions executed in the application (dynamic instruction execution profile)

Poll: **What are the units of (instructions executed x CPI x clock period)?**

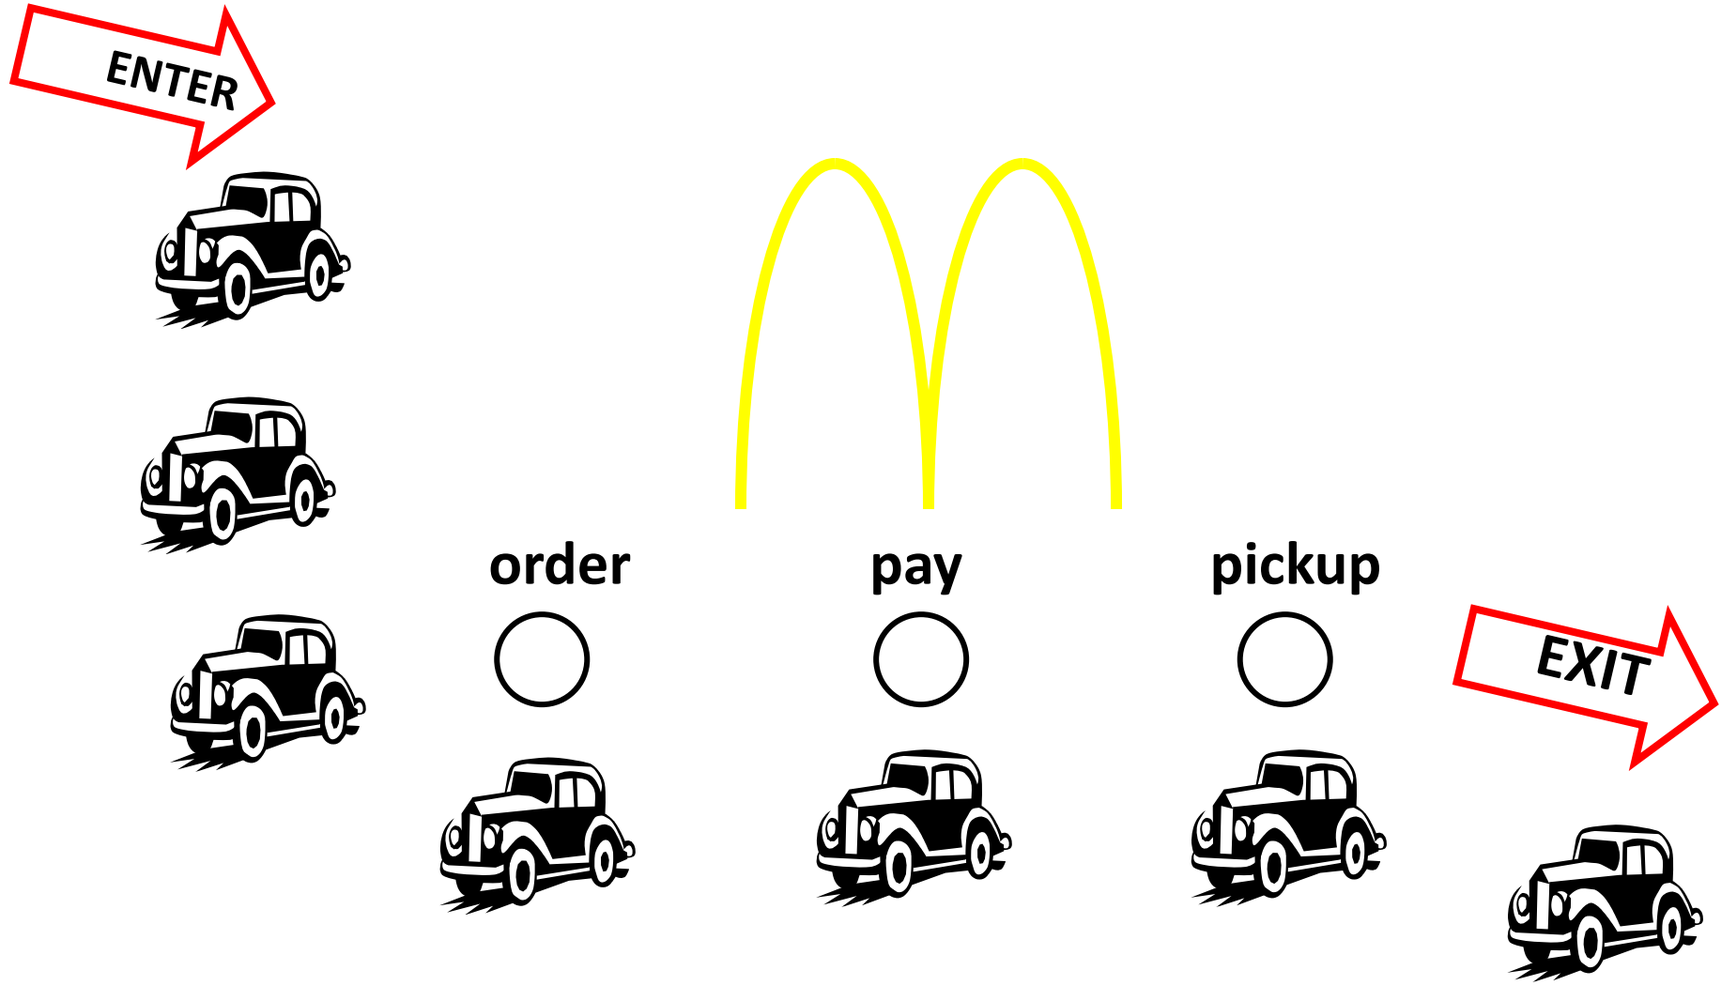
Datapath Summary

- Single-cycle processor
  - CPI = 1 (by definition)
  - clock period = ~10 ns
- Multi-cycle processor
  - CPI = ~4.25
  - clock period = ~2 ns
- Better design:
  - CPI = 1
  - clock period = ~2ns
- How??
  - Work on multiple instructions at the same time

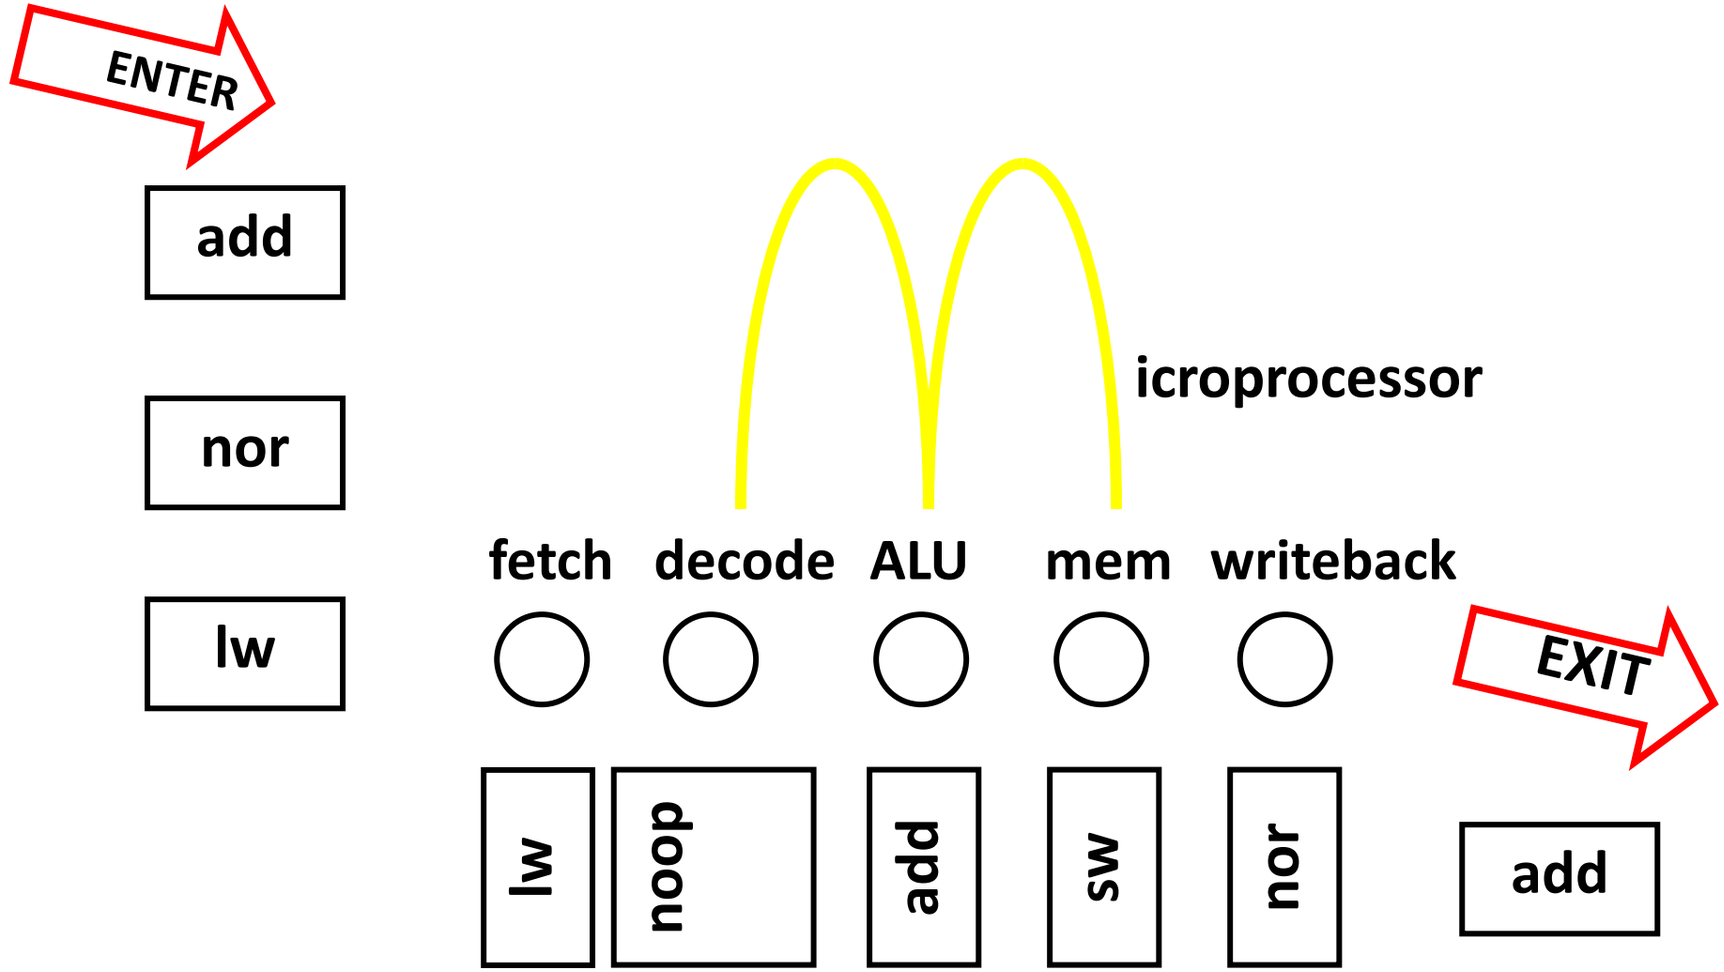
Pipelining

- Want to execute an instruction?
  - Build a processor (multi-cycle)
  - Find instructions
  - Line up instructions (1, 2, 3, …)
  - Overlap execution
    - Cycle #1: Fetch 1
    - Cycle #2: Decode 1 Fetch 2
    - Cycle #3: ALU 1 Decode 2 Fetch 3
    - . . . . . .
  - This is called pipelining instruction execution.
  - Used extensively for the first time on IBM 360 (1960s).
  - CPI approaches 1.

Pipelining



Pipelining



ENTER
add

add

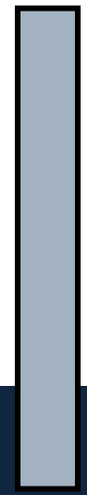
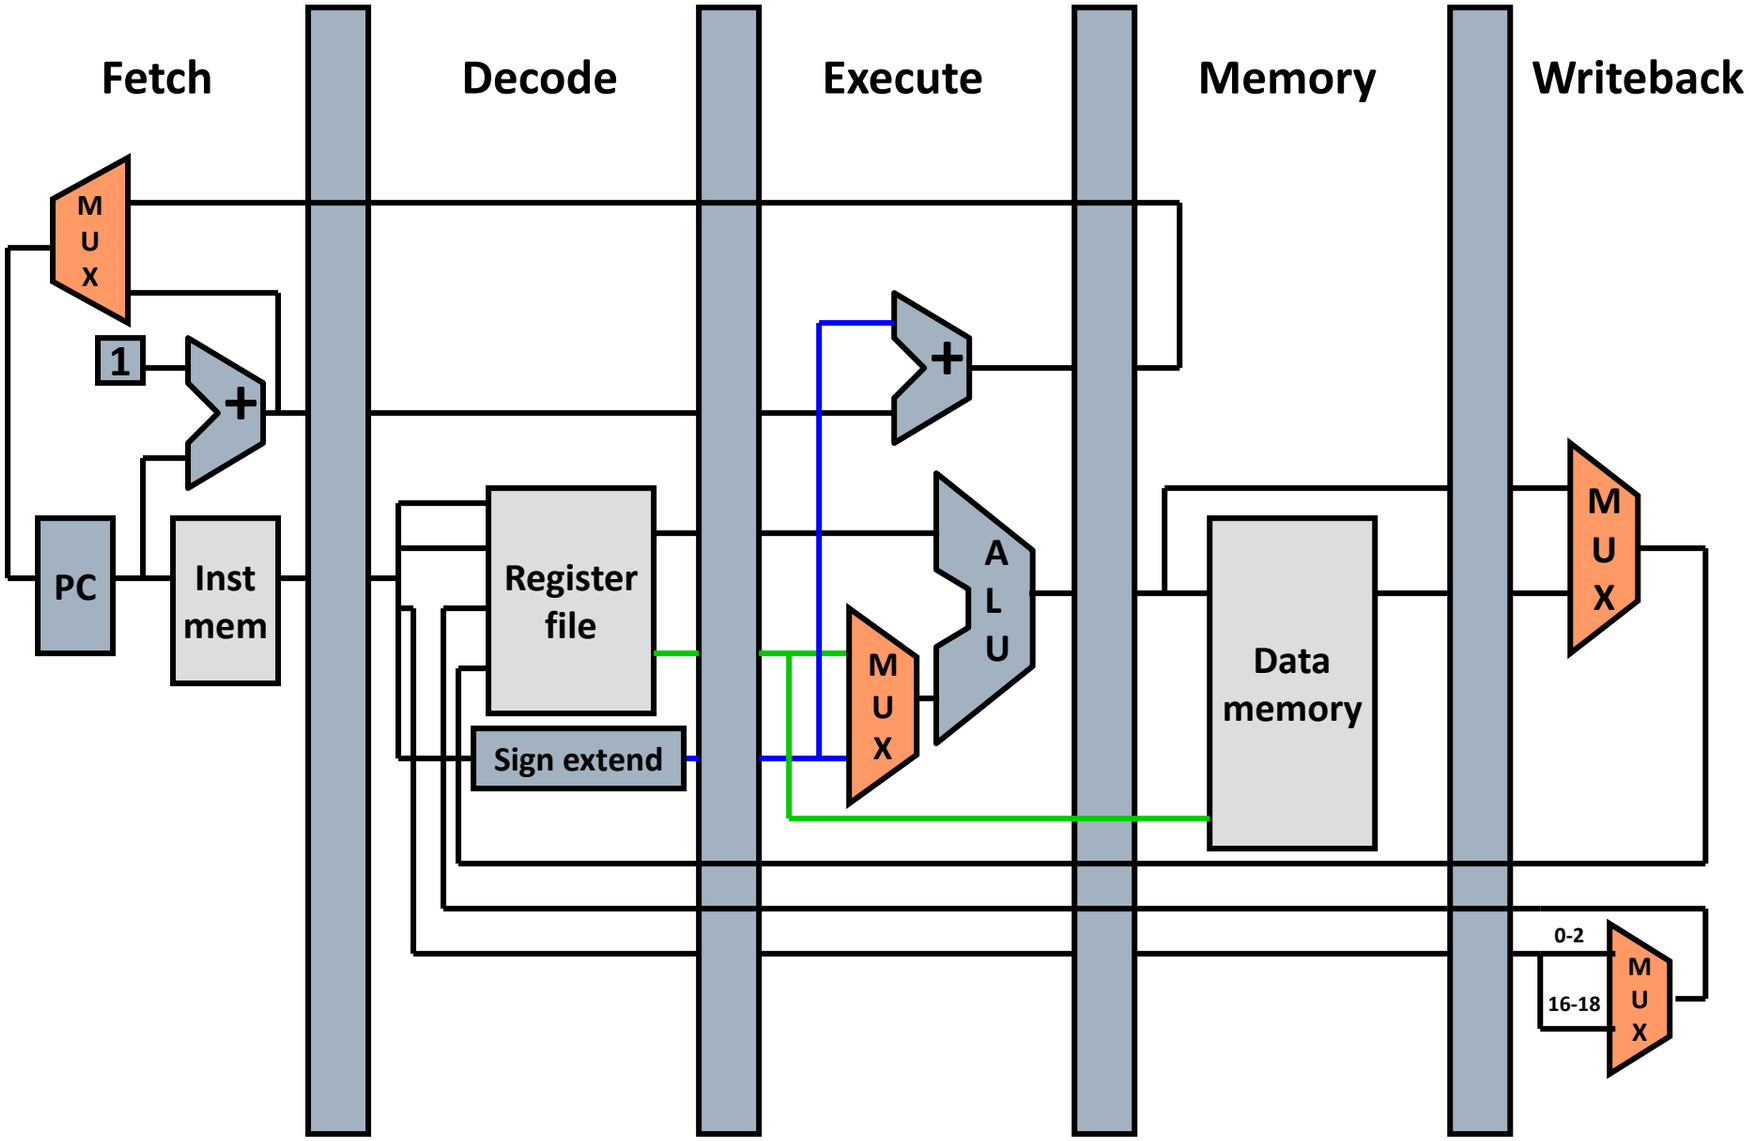
Pipelined implementation of LC2K

- Break the execution of the instruction into cycles.
  - Similar to the multi-cycle datapath
- Design a separate datapath stage for the execution performed during each cycle.
  - Build pipeline registers to communicate between the stages.
  - Whatever is on the left gets written onto the right during the next cycle
  - Kinda like the **Instruction Register** in our multi-cycle design, but we'll need one for each stage



Our new pipelined datapath



Next time

- More pipelining
- Lingering questions / feedback? I'll include an anonymous form at the end of every lecture: https://bit.ly/3oXr4Ah
